

REPORT OF THE COUNCIL ON MEDICAL SERVICE

CMS Report 7-A-10

Subject: Shared Decision-Making

Presented by: Barbara L. McAneny, MD, Chair

Referred to: Reference Committee A
(Glenn A. Loomis, MD, Chair)

1 As efforts to promote greater efficiency in the health care system intensify, more attention is being
2 given to the role and responsibility of the patient in determining how health care resources should
3 be used. Policymakers hope that a renewed focus on “patient-centered care” will help increase the
4 value of health care spending in the United States, while also maximizing clinical quality. One
5 concept that is gaining attention is the use of formal shared decision-making tools to help increase
6 patient engagement in medical decisions when there are several clinically-appropriate options from
7 which to choose. The Patient Protection and Affordable Care Act of 2010 (P.L. 111-148) includes
8 provisions to facilitate and encourage the use of the shared decision-making process.

9

10 At the 2008 Interim Meeting, the House of Delegates established policy, directing the American
11 Medical Association (AMA) to educate and communicate to physicians about the importance of
12 shared decision-making guidance as a tool to advance patient-centered care (D-373.999, AMA
13 Policy Database). This report was initiated by the Council to describe formal shared decision-
14 making; discuss the design and development of patient decision aids; and summarize quality
15 standards that have been developed to evaluate patient decision aids. The report also addresses
16 potential benefits and limitations associated with the use of formal shared decision-making
17 processes, and makes recommendations regarding future developments in this field.

18

19 BACKGROUND

20

21 According to the AMA *Code of Medical Ethics*, the principle of informed consent requires that
22 physicians “present medical facts accurately to the patient...and make recommendations for
23 management in accordance with good medical practice” (Opinion E-8.08). The concept of shared
24 decision-making builds on this definition by fostering an environment in which patients have the
25 opportunity to evaluate their medical options in accordance with personal preferences and values.
26 The Foundation for Informed Medical Decision-Making, a non-profit organization based in Boston,
27 Massachusetts, defines shared decision-making as “the process by which a health care provider
28 communicates to the patient personalized information about the options, outcomes, probabilities,
29 and scientific uncertainties of available treatment options and the patient communicates his or her
30 values and the relative importance he or she places on benefits and harms.” Although patients
31 always have the right to participate in decisions about their medical treatment, using formal shared
32 decision-making processes can be especially useful in cases where more than one treatment option
33 is available, and no treatment is considered “best” according to clinical evidence.

1 SHARED DECISION-MAKING AND PATIENT DECISION AIDS

2
3 Formal shared decision-making processes are generally facilitated through the use of electronic or
4 paper-based patient decision support aids, which are often developed by third parties and licensed
5 for use by health plans, hospitals or physicians. Through tools such as booklets, videos, interactive
6 computer programs, and structured personal coaching, patients receive evidence-based information
7 about treatment options and outcomes that is specifically designed to help them evaluate tradeoffs
8 in the context of their own feelings and preferences. Decision support aids supplement direct
9 communication between the physician and patient by offering patients an opportunity to process
10 complex – and possibly frightening – information at their own pace, using information that
11 addresses the emotional as well as the clinical aspects of medical care.

12
13 Patient decision aids have three core elements: clinical information, “values clarification,” and
14 guidance to help patients make and communicate their treatment decisions (O’Connor, 2004). The
15 clinical information component represents a synthesis of relevant evidence-based information
16 about the patient’s medical condition, available treatment options, and the potential risks, benefits,
17 and outcomes associated with each option. The clinical information should reinforce what a patient
18 has already learned from his or her physician, and give the patient the opportunity to consider the
19 information in a different way, without being influenced by conscious or unconscious biases on the
20 part of the physician.

21
22 The “values clarification” component of patient decision aids helps patients quantify the more
23 subjective elements of addressing their medical condition and pursuing a course of treatment. The
24 decision aids are designed to help patients learn about and identify with the physical, emotional and
25 social aspects of each treatment option, so that they can visualize how their life might be affected
26 by various treatments. Decision aids often use testimonials from actual patients to offer balanced
27 examples of how and why different people made different treatment choices. Another element of
28 values clarification could involve the use of questionnaire-type tools to help patients consider and
29 articulate their priorities in evaluating their choices (e.g., maximize convenience, minimize pain,
30 extend life expectancy).

31
32 The guidance and communication element of patient decision aids helps lead patients through the
33 process of synthesizing the clinical and values information that they have obtained and making a
34 decision that they are comfortable with. Entities that develop patient decision aids often market
35 them similarly to disease management programs and may include personalized coaching by a nurse
36 or other professional to help guide patients through the whole process. In some cases, especially in
37 very sensitive areas such as decisions about end-of-life care, decision support aids have been
38 designed to help structure and improve patient-physician conversations *per se*, with the physician
39 taking the explicit role of professional guide.

40
41 In clinical practice, physicians determine what conditions and which patients could benefit from
42 engaging in a formal shared decision-making process. In cases where evidence-based, best practice
43 guidelines establish the preferred method of treatment, patients generally benefit from accepting
44 the recommendation of their physician, and a formal shared decision-making process is not
45 necessary. Similarly, some patients may be unwilling or unable to assume increased responsibility
46 for their medical decision-making, and prefer to act on the recommendations of their physician, no
47 matter what the circumstances. For these patients, the formal shared decision-making process
48 could become overwhelming, and actually jeopardize rather than enhance the patient-physician
49 relationship.

1 For more engaged patients with medical conditions that have more ambiguous treatment protocols,
2 shared decision-making can facilitate and promote the delivery of patient-centered care. Where
3 appropriate, physicians may “prescribe” a decision support aid for a patient diagnosed with a
4 clinical condition that can be treated in multiple ways. For example, if a patient is diagnosed with
5 prostate cancer the doctor might recommend that the patient use a decision support aid to help
6 clarify the patient’s understanding of the condition and possible treatment options. Because there
7 is no clinical consensus on the preferred treatment (or non-treatment) of prostate cancer, the shared
8 decision-making process can be a valuable tool in helping patients understand and accept the
9 course of treatment that is most appropriate for them. Ideally patients will use the decision support
10 tool before their next medical visit, so that they are in a better position to discuss and choose
11 treatment options with their doctors.

12

13 QUALITY STANDARDS FOR PATIENT DECISION AIDS

14

15 Patient decision aids or decision support tools are intended to be much more comprehensive than
16 standard patient information materials that are widely available in health care settings or online.
17 Typical patient flyers generally provide brief, easily understood, factual information about a
18 medical condition or procedure. In contrast, patient decision aids are designed to engage patients
19 in a process of learning about their health and treatment options. Assuring the clinical quality and
20 ethical design of patient decision aids will become increasingly important as the concept of shared
21 decision-making gains popularity.

22

23 The International Patient Decision Aids Standards (IPDAS) Collaboration is a multi-disciplinary
24 effort to establish an internationally approved set of criteria for evaluating the quality of patient
25 decision aids. Led by researchers from Canada and the United Kingdom, researchers, practitioners,
26 patients and policymakers from 14 countries used online tools to establish a consensus on criteria
27 that could be used to measure the reliability of a decision aid. The researchers identified evaluation
28 criteria in three broad areas: content, development process, and effectiveness. Within each of those
29 areas, the IPDAS instrument (IPDASi) identifies specific elements that should be evaluated to
30 determine the comprehensiveness and integrity of the tool. Among these evaluation elements are
31 whether the tool adequately describes the health condition and all treatment options (including no
32 treatment); what methods are used to help patients clarify values; whether a systematic
33 development process followed; how developer credentials are documented and scientific evidence
34 verified; and how conflicts of interest are identified and handled.

35

36 The IPDAS Collaboration is currently piloting a service through which developers of patient
37 decision aids can have their product evaluated using the IPDASi. The National Committee for
38 Quality Assurance (NCQA) has communicated with the IPDAS Collaboration steering committee
39 about the possibility of developing accreditation standards for decision aids or the process of using
40 them. In 2009, the IPDAS Collaboration received funding from the Foundation for Informed
41 Medical Decision Making to conduct research correlating the results of randomized trials against
42 the IPDASi ratings, and to establish a “must have” set of quality criteria for patient decision aids.

43

44 The Ottawa Health Research Institute (OHRI) also has a research group dedicated to patient
45 decision aids, led by Annette O’Connor, a leading IPDAS Collaboration researcher. The group
46 designs and tests patient decision aids, and conducts research on the decision support needs of
47 patients and physicians, tools that measure the quality of decision support services, and the cost-
48 effectiveness of decision support-service models. OHRI’s Web site is an excellent resource for
49 information about the development and implementation of patient decision aids. The site includes
50 detailed “toolkits” and tutorials to help integrate the use of decision aids into clinical practice. The

1 Web site also includes an “A – Z” listing of available decision aids by topic, along with results
2 from IPDASi evaluations, if applicable.

3
4 The Council believes it is important to emphasize that shared decision-making protocols and
5 patient decision support aids are to be used in conjunction with, not as a replacement for, physician
6 consultation. Physician guidance regarding the appropriate use of decision support aids, and
7 communication between patient and physician about the patient’s values (as clarified through
8 decision aids), are critical components of a comprehensive and effective shared decision-making
9 process.

10
11 **OPPORTUNITIES AND RISKS ASSOCIATED WITH FORMAL SHARED DECISION-**
12 **MAKING**

13
14 Formal shared decision-making processes and patient decision aids are potentially useful tools to
15 help the US move toward more patient-centered care, which has the potential to improve the
16 overall quality and efficiency of the health care system. Patients using formal decision support
17 tools often report more comfort and satisfaction with their treatment decisions (O’Connor, 2004).
18 Greater patient responsibility and engagement in developing their treatment plans might also lead
19 to improved adherence and long term health outcomes, reducing wasteful spending associated with
20 patient non-adherence.

21
22 Research also shows that patients using decision support tools tend to have more realistic
23 expectations of the outcomes or results of their treatment choice. Formal shared decision-making
24 programs might reduce tension between patients and physicians and limit a patient’s feeling that
25 his or her doctor may have made the wrong treatment choice, especially if the outcome is
26 unexpected or disappointing. Accordingly, well designed and documented shared decision-making
27 processes could help improve the medical liability climate for physicians and reduce the amount of
28 waste associated with spending on defensive medicine.

29
30 Although there is some evidence to suggest that patients sometimes choose less invasive treatments
31 when they evaluate their options using formal decision support tools, it is premature – and
32 potentially dangerous – to suggest that the use of patient decision aids will reduce demand for
33 medical services. The “efficiency” of the health care system can be improved through the use of
34 shared decision-making processes to the extent that patients are better able to make decisions based
35 on a full understanding of evidence and their individual preferences. The Council has previously
36 emphasized the importance of pursuing policy initiatives that encourage better value for health care
37 spending, rather than those with the primary goal of reducing costs. Effectively designed and
38 implemented formal shared decision-making initiatives have the potential to yield better value for
39 health care spending by creating a mechanism that incorporates patient preferences in health care
40 resource use determinations.

41
42 A potential risk associated with the promotion of formal shared decision-making processes is that
43 they could be used by insurers and others as a tool to reduce costs. Decision support tools could be
44 created that are misleading or biased toward or against certain treatment choices, in an effort to
45 encourage patients to choose less expensive options. Even in choosing what questions to ask, and
46 how to ask them, it might be possible to subtly influence patient choices in an inappropriate
47 manner. This risk makes the independence of groups creating these tools and the use of quality
48 control measures especially important. In addition, implementation of mandatory or rigid decision-
49 making protocols could create another administrative burden for physicians and another barrier to
50 patient-centered care. Tools should be designed and implemented to aid physicians and patients,

1 rather than as a requirement for approval for insurance coverage, or as a means to steer patients
 2 toward a particular treatment option.

3
 4 Successful use of patient decision aids and implementation of shared decision-making processes
 5 depends on the ability of physicians to effectively integrate the tools into their practices. Even if
 6 the decision aids are provided through a patient’s health insurance, in many cases physicians will
 7 need to spend more time communicating with their patients and leading them through the decision
 8 processes. For some physicians, communicating with patients about values and preferences will
 9 involve new skills. Many practices may find it challenging to adopt shared decision-making
 10 protocols without additional funding and resources to support their use.

11
 12 As noted, shared decision-making might not be an appropriate process for all patients. Some
 13 patients might not want to use decision aids and may feel overwhelmed by the extent of the
 14 information provided or confused by the process of clarifying their values. Physicians play a
 15 critical role in evaluating the appropriateness of offering or initiating a formal shared decision-
 16 making process based on the patient’s clinical as well as personal needs.

17
 18 **DISCUSSION**

19
 20 The idea of incorporating formal shared decision-making processes into medical practice is
 21 attracting increasing attention from the health policy and medical communities. Efforts are being
 22 made to promote shared decision-making, while simultaneously enhancing the depth and breadth of
 23 research into the value of implementing shared decision-making processes on a larger scale. The
 24 Foundation for Medical Decision Making sponsors demonstration projects at 11 primary care and
 25 four specialty care sites to learn how decision support tools can be effectively integrated into
 26 medical practice, and how their use affects the decision-making process. In addition, hospitals and
 27 clinics in nine states are participating with the Foundation and HealthDialog (a non-profit
 28 organization that provides decision support tools) in a breast cancer initiative to support shared
 29 decision making at all major points in breast cancer treatment.

30
 31 The 2010 Patient Protection and Affordable Care Act included provisions to support the use of
 32 shared decision-making specifically in the context of “preference sensitive care” (i.e., medical care
 33 for which the clinical evidence does not clearly support one treatment option). The Act gives the
 34 Secretary of Health and Human Services the authority to contract with an independent entity to
 35 endorse patient decision aids and establish standards for them. It also directs the Secretary to
 36 develop a program to award grants or contracts to entities to develop, test and educate providers on
 37 the use of patient decision aids. Additional grants will be available to establish Shared Decision-
 38 Making Resource Centers “to provide technical assistance to providers and to develop and
 39 disseminate best practices and other information to support and accelerate adoption,
 40 implementation and effective use of patient decision aids and shared decision-making by
 41 providers.” Grants will also be available for health care providers to develop, implement and
 42 assess shared decision-making techniques.

43
 44 In addition to federal support for the concept of shared decision-making, individual states have also
 45 been exploring its use. Washington state recently passed legislation authorizing the creation of a
 46 shared decision-making demonstration project, to be conducted at group practice sites providing
 47 health care through state-based contracts. The demonstration projects will include an evaluation of
 48 various aspects of the shared decision-making process and use of patient decision aids. These
 49 projects will assess patient understanding of treatment options, alignment between patient values
 50 and the care they receive, and the cost-effectiveness of shared decision-making in clinical practice.
 51 At the time this report was developed, other states were considering similar legislation.

1 The Council is encouraged by the potential of shared decision-making processes to further enhance
2 the patient-physician relationship and to help improve the quality and overall value of health care
3 in the United States. Data and information from demonstration projects and other targeted research
4 will provide important guidance for physicians and the medical profession regarding the
5 appropriate use of these tools and the most effective and efficient ways of integrating them into
6 medical practice. The Council will continue to monitor developments in this field to ensure that
7 implementation and application of shared decision-making processes remain voluntary for patients
8 and physicians, and that effective and reliable evaluation processes are in place to ensure the
9 integrity and utility of the information provided to patients.

10
11 RECOMMENDATIONS

12
13 The Council on Medical Service recommends that the following be adopted and that the remainder
14 of the report be filed.

- 15
16 1. That our American Medical Association recognize the formal shared decision-making
17 process as having three core elements to help patients become active partners in their
18 health care:
19
20 a. clinical information about health conditions, treatment options, and potential
21 outcomes;
22
23 b. tools to help patients identify and articulate their values and priorities when choosing
24 medical treatment options; and
25
26 c. structured guidance to help patients integrate clinical and values information to make
27 an informed treatment choice. (New HOD Policy)
28
29 2. That our AMA support the concept of voluntary use of shared decision-making processes
30 and patient decision aids as a way to strengthen the patient-physician relationship and
31 facilitate informed patient engagement in health care decisions. (New HOD Policy)
32
33 3. That our AMA oppose any efforts to require the use of patient decision aids or shared
34 decision-making processes as a condition of health insurance coverage or provider
35 participation. (New HOD Policy)
36
37 4. That our AMA support the development of demonstration and pilot projects to help
38 increase knowledge about integrating shared decision-making tools and processes into
39 clinical practice. (New HOD Policy)
40
41 5. That our AMA support efforts to establish and promote quality standards for the
42 development and use of patient decision aids, including standards for physician
43 involvement in development and evaluation processes, clinical accuracy, and conflict of
44 interest disclosures. (New HOD Policy)
45
46 6. That our AMA continue to study the concept of shared decision-making and report back to
47 the House of Delegates regarding developments in this area. (Directive to Take Action)

Fiscal Note: Staff cost estimated to be less than \$500 to implement.
