Technical skill required	3.26	3.29
Physical effort required	2.89	3.08
Psychological Stress (Mean)		
The risk of significant complications, morbidity and/or mortality	3.00	3.03
Outcome depends on the skill and judgment of physician	3.34	3.25
Estimated risk of malpractice suit with poor outcome	3.01	3.04

INTENSITY/COMPLEXITY MEASURES	CPT Code	Reference Service 1
Time Segments (Mean)		
Pre-Service intensity/complexity	2.86	2.91
Intra-Service intensity/complexity	3.10	3.17
Post-Service intensity/complexity	2.80	2.92

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 66 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. The CP reviewed the survey time for intra-service and agrees that this time was overestimated and therefore recommends the 25th percentile for intra-service time, 14 minutes. Further, the CP recommends that 5 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

The CP reviewed the surveyed code in comparison to the key reference code 12002 (Work RVU=1.14) and noted that the reference code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code. Further, the CP noted that the intra-service time for the reference code exceeds the intra-service time for the surveyed code, 15 minutes and 14 minutes.

In addition, the CP compared the surveyed code to MPC code 11100 (work RVU=0.81). The CP noted that the 11100 has 22 minutes of total service time and the surveyed code has 25 minutes of total service time.

		Pre	Intra	Post	Total	RVU
K-Ref	12002	7	15	5	27	1.14
SVY	11306	6	14	5	25	1.18
MPC	11100	5	12	5	22	0.81

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 11306

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)

If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Podiatry How often? Sometimes

Specialty Family Practice How often? Rarely

Estimate the number of times this service might be provided nationally in a one-year period? 313050
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimated 3x Medicare Utilization

Specialty Dermatology Frequency 143252 Percentage 45.76 %

Specialty Podiatry Frequency 121151 Percentage 38.70 %

Specialty Family Practice, PAs etc Frequency 48648 Percentage 15.54 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 104,350
If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Dermatology Frequency 47751 Percentage 45.76 %

Specialty Podiatry Frequency 40384 Percentage 38.70 %

Specialty Family Practice, PAs etc Frequency 16216 Percentage 15.54 %

Do many physicians perform this service across the United States? Yes

---

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 11306

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:11307 Tracking Number Original Specialty Recommended RVU: 1.20
Presented Recommended RVU: 1.20
Global Period: 000 RUC Recommended RVU: 1.20

CPT Descriptor: Shaving of epidermal or dermal lesion, single lesion, scalp, neck, hands, feet, genitalia; lesion diameter 1.1 to 2.0 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A 40 year old female presents for the removal of an atypical pigmented lesion on her scalp with a diameter of 1.6 cm. The lesion warrants complete removal for thorough pathologic evaluation.

Percentage of Survey Respondents who found Vignette to be Typical: 47%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: Positioning: Based upon lesion location and the technical detail required of the procedure, the patient is positioned for maximum flexibility for the surgeon while maintaining patient comfort. Records are checked to confirm patient, procedure and site. A photograph of the lesion is taken, printed and scanned/inserted into the patient's chart. The area is prepped, anaesthetized and draped. Anesthesia is injected in both subcutaneous and dermal compartments so that it results in a "raising" of the lesion to facilitate appropriate dermal depth removal.

Description of Intra-Service Work: Based on lesion type, size, and skin location, relaxed skin tension lines are marked. The dermal thickness in the location is evaluated, and then a margin between 2 to 5 mm is delineated with a surgical marker. The outline of the mark is scored using a scalpel. Starting at one end of the lesion the dermis is incised at anywhere from a 30 to 60 degree angle, to coincide with the leading edge of the skin lesion and to ensure that the path of removal is fully under the lesion yet still in the dermis. Hemostasis is achieved as needed, usually with pressure or topical application of aluminum chloride. The angle of dissection is then straightened to run parallel to the axis of the lesion, while remaining in the dermis. The shave proceeds forward following the pre-determined marked outline. As the dissection proceeds, the lesion is retracted as needed. This is accomplished by the placement of an initial suture to mark a border or retraction hooks or non-crushing forceps. The suture location is documented. As the midpoint is reached the dermal depth is checked to ensure that the fat is not penetrated and that the lesion appears in the entirety of the removed sample. Following the outline and maintaining a 30 to 60% transverse exit angle the lesion is removed. Additional hemostasis is achieved as above. Should further hemostasis need to be achieved, a fast-absorbing suture ligature or electrocautery can be utilized.

Description of Post-Service Work: The treatment site is monitored for delayed bleeding. An appropriate dressing for location and size is chosen (larger lesions might require Duoderm or some other flexible temporary skin substitute) and applied. Side effects, including pain, infection, oozing, and scaring are once again discussed with the patient, and the patient is discharged

with appropriate analgesics and wound care instructions. The specimen is sent to pathology with a request for thorough examination.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 66 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. Further, the CP recommends that 5 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

The CP reviewed the surveyed code in comparison to the key reference code 12002 (Work RVU=1.14) and noted that the surveyed code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code. Further, the CP noted that the total service time for the surveyed code exceeds the total service time for the reference code, 34 minutes and 27 minutes.

In addition, the CP compared the surveyed code to MPC code 11755 (work RVU=1.31). The CP noted that the 11755 has 55 minutes of total service time and the surveyed code has 34 minutes of total service time.

		Pre	Intra	Post	Total	RVU
MPC	11755	15	25	15	55	1.31
SVY	11307	6	21	5	32	1.20
K-Ref	12002	7	15	5	27	1.14

Based on these comparisons, the CP recommends 1.20 work RVUs, the 25th percentile for 11307.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 11307

Description of Pre-Service Work: Positioning: Based upon lesion location and the technical detail required of the procedure, the patient is positioned for maximum flexibility for the surgeon while maintaining patient comfort. Records are checked to confirm patient, procedure and site. A photograph of the lesion is taken, printed and scanned/inserted into the patient's chart. The area is prepped, anaesthetized and draped. Anesthesia is injected in both subcutaneous and dermal compartments so that it results in a "raising" of the lesion to facilitate appropriate dermal depth removal.

Description of Intra-Service Work: Based on lesion type, size, and skin location, relaxed skin tension lines are marked. The dermal thickness in the location is evaluated, and then a margin between 2 to 5 mm is delineated with a surgical marker. The outline of the mark is scored using a scalpel. Starting at one end of the lesion the dermis is incised at anywhere from a 30 to 60 degree angle, to coincide with the leading edge of the skin lesion and to ensure that the path of removal is fully under the lesion yet still in the dermis. Hemostasis is achieved as needed, usually with pressure or topical application of aluminum chloride. The angle of dissection is then straightened to run parallel to the axis of the lesion, while remaining in the dermis. The shave proceeds forward following the pre-determined marked outline. As the dissection proceeds, the lesion is retracted as needed. This is accomplished by the placement of an initial suture to mark a border or retraction hooks or non-crushing forceps. The suture location is documented. As the midpoint is reached the dermal depth is checked to ensure that the fat is not penetrated and that the lesion appears in the entirety of the removed sample. Following the outline and maintaining a 30 to 60% transverse exit angle the lesion is removed. Additional hemostasis is achieved as above. Should further hemostasis need to be achieved, a fast-absorbing suture ligature or electrocautery can be utilized.

Description of Post-Service Work: The treatment site is monitored for delayed bleeding. An appropriate dressing for location and size is chosen (larger lesions might require Duoderm or some other flexible temporary skin substitute) and applied. Side effects, including pain, infection, oozing, and scaring are once again discussed with the patient, and the patient is discharged

with appropriate analgesics and wound care instructions. The specimen is sent to pathology with a request for thorough examination.

Time Segments (Mean)		
Pre-Service intensity/complexity	3.52	3.17
Intra-Service intensity/complexity	3.91	3.50
Post-Service intensity/complexity	3.50	3.27

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 66 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. Further, the CP recommends that 7 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

The CP reviewed the surveyed code in comparison to the key reference code 12002 (Work RVU=1.14) and noted that the surveyed code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code. Further, the CP noted that the total service time for the surveyed code exceeds the total service time for the reference code, 39 minutes and 27 minutes.

In addition, the CP compared the surveyed code to MPC code 29445 (work RVU=1.78). The CP noted that the 29445 has 50 minutes of total service time and the surveyed code has 37 minutes of total service time.

		Pre	Intra	Post	Total	RVU
MPC	29445	15	30	5	50	1.78
SVY	11308	6	26	5	37	1.46
K-Ref	12002	7	15	5	27	1.14

Based on these comparisons, the CP recommends 1.46 work RVUs, the 25th percentile for 11308.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 11308

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Podiatry How often? Commonly

Specialty Dermatology How often? Sometimes

Specialty Family Practice How often? Rarely

Estimate the number of times this service might be provided nationally in a one-year period? 34167
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimate 3X MedicareUtilization

Specialty pODIATRY Frequency 18594 Percentage 54.42 %

Specialty Dermatology Frequency 10934 Percentage 32.00 %

Specialty Family Practice, Plastics etc Frequency 4640 Percentage 13.58 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 11,389 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Podiatry Frequency 6198 Percentage 54.42 %

Specialty Dermatology Frequency 3645 Percentage 32.00 %

Specialty Family Practice, Plastics etc Frequency 1547 Percentage 13.58 %

Do many physicians perform this service across the United States? Yes

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:11310 Tracking Number Original Specialty Recommended RVU: 0.80
Presented Recommended RVU: 0.80
Global Period: 000 RUC Recommended RVU: 1.19

CPT Descriptor: Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter 0.5 cm or less

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A 40 year old female presents for the removal of an atypical pigmented lesion on her cheek with a diameter of 0.4cm. The lesion warrants complete removal for thorough pathologic evaluation.

Percentage of Survey Respondents who found Vignette to be Typical: 90%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: Positioning: Based upon lesion location and the technical detail required of the procedure, the patient is positioned for maximum flexibility for the surgeon while maintaining patient comfort. Records are checked to confirm patient, procedure and site. A photograph of the lesion is taken, printed and scanned/inserted into the patient's chart. The area is prepped, anaesthetized and draped. Anesthesia is injected in both subcutaneous and dermal compartments so that it results in a "raising" of the lesion to facilitate appropriate dermal depth removal.

Description of Intra-Service Work: Based on lesion type, size, and skin location, relaxed skin tension lines are marked. The dermal thickness in the location is evaluated, and then a margin between 2 to 5 mm is delineated with a surgical marker. The outline of the mark is scored using a scalpel. Starting at one end of the lesion the dermis is incised at anywhere from a 30 to 60 degree angle, to coincide with the leading edge of the skin lesion and to ensure that the path of removal is fully under the lesion yet still in the dermis. Hemostasis is achieved as needed, usually with pressure or topical application of aluminum chloride. The angle of dissection is then straightened to run parallel to the axis of the lesion, while remaining in the dermis. The shave proceeds forward following the pre-determined marked outline. As the dissection proceeds, the lesion is retracted as needed. This is accomplished by the placement of an initial suture to mark a border or retraction hooks or non-crushing forceps. The suture location is documented. As the midpoint is reached the dermal depth is checked to ensure that the fat is not penetrated and that the lesion appears in the entirety of the removed sample. Following the outline and maintaining a 30 to 60% transverse exit angle the lesion is removed. Additional hemostasis is achieved as above. Should further hemostasis need to be achieved, a fast-absorbing suture ligature or electrocautery can be utilized.

Description of Post-Service Work: The treatment site is monitored for delayed bleeding. An appropriate dressing for location and size is chosen (larger lesions might require Duoderm or some other flexible temporary skin substitute) and applied. Side effects, including pain, infection, oozing, and scaring are once again discussed with the patient, and the patient is discharged

with appropriate analgesics and wound care instructions. The specimen is sent to pathology with a request for thorough examination.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 68 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. Further, the CP recommends that 5 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

Although, the CP noted that the total service time for the surveyed code has less total service time as compared to the reference code is 33 minutes and 36 minutes, respectively. Further, the CP reviewed the surveyed code in comparison to the key reference code 11440 (Work RVU=1.05) and noted that the reference code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code.

In addition, the CP compared the surveyed code to MPC code 20551 (work RVU=0.75). The CP noted that the 20551 has 20 minutes of total service time and the surveyed code has 31 minutes of total service time.

		Pre	Intra	Post	Total	RVU
K-RSL	11440	5	10	5	36	1.05
SVY	11310	6	20	5	31	1.18
MPC	20551	10	5	5	20	0.75

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

Description of Intra-Service Work: Based on lesion type, size, and skin location, relaxed skin tension lines are marked. The dermal thickness in the location is evaluated, and then a margin between 2 to 5 mm is delineated with a surgical marker. The outline of the mark is scored using a scalpel. Starting at one end of the lesion the dermis is incised at anywhere from a 30 to 60 degree angle, to coincide with the leading edge of the skin lesion and to ensure that the path of removal is fully under the lesion yet still in the dermis. Hemostasis is achieved as needed, usually with pressure or topical application of aluminum chloride. The angle of dissection is then straightened to run parallel to the axis of the lesion, while remaining in the dermis. The shave proceeds forward following the pre-determined marked outline. As the dissection proceeds, the lesion is retracted as needed. This is accomplished by the placement of an initial suture to mark a border or retraction hooks or non-crushing forceps. The suture location is documented. As the midpoint is reached the dermal depth is checked to ensure that the fat is not penetrated and that the lesion appears in the entirety of the removed sample. Following the outline and maintaining a 30 to 60% transverse exit angle the lesion is removed. Additional hemostasis is achieved as above. Should further hemostasis need to be achieved, a fast-absorbing suture ligature or electrocautery can be utilized.

Description of Post-Service Work: The treatment site is monitored for delayed bleeding. An appropriate dressing for location and size is chosen (larger lesions might require Duoderm or some other flexible temporary skin substitute) and applied. Side effects, including pain, infection, oozing, and scaring are once again discussed with the patient, and the patient is discharged

with appropriate analgesics and wound care instructions. The specimen is sent to pathology with a request for thorough examination.

SURVEY DATA

RUC Meeting Date (mm/yyyy)	04/2012				
Presenter(s):	Mark Kaufmann, MD; Brett Coldiron, MD				
Specialty(s):	American Academy of Dermatology

INTENSITY/COMPLEXITY MEASURES	CPT Code	Reference Service 1
Time Segments (Mean)		
Pre-Service intensity/complexity	2.90	2.81
Intra-Service intensity/complexity	3.20	3.25
Post-Service intensity/complexity	2.90	2.94

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 68 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. The CP reviewed the survey time for intra-service and agrees that this time was overestimated and therefore recommends the 25th percentile for intra-service time, 16 minutes. Further, the CP recommends that 5 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

The CP reviewed the surveyed code in comparison to the key reference code 12013 (Work RVU=1.22) and noted that the reference code and the surveyed code require similar mental effort and judgment, technical skill, physical effort and overall similarly intense services to perform. Further, the CP noted that the intra-service time for the reference code is similar to the intra-service time for the surveyed code, 15 minutes and 16 minutes. Despite the similarity in time and intensity, the CP recommends a value slightly less than the current value of the key reference code.

In addition, the CP compared the surveyed code to MPC code 12011 (work RVU=1.07). The CP noted that the 12011 has 24 minutes of total service time and the surveyed code has 29 minutes of total service time. Further, the CP compared the surveyed code to reference code 11730 (Work RVU=1.10). The CP noted that despite the same value, the MPC code had a longer total time as compared to the surveyed code, 37 minutes and 27 minutes.

		Pre	Intra	Post	Total	RVU
K-Ref	12013	7	15	5	27	1.22
Ref	11730	15	12	10	37	1.10
SVY	11311	6	16	5	27	1.43
MPC	12011	7	12	5	24	1.07

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 11311

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Family Practice How often? Rarely

Specialty Plastic & Reconstructive Surgery How often? Rarely

Estimate the number of times this service might be provided nationally in a one-year period? 359280
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimate 3X Medicare Utilization

Specialty Dermatology Frequency 260155 Percentage 72.41 %

Specialty Family Practice Frequency 23821 Percentage 6.63 %

Specialty Plastics, PAs etc Frequency 75306 Percentage 20.96 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 119,760
If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Meciare Claims Data

Specialty Dermatology Frequency 86719 Percentage 72.41 %

Specialty Family Practice Frequency 7941 Percentage 6.63 %

Specialty Plastics, PAs etc Frequency 25102 Percentage 20.96 %

Do many physicians perform this service across the United States? Yes

---

Professional Liability Insurance Information (PLI)

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 11311

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:11312 Tracking Number

Original Specialty Recommended RVU: 1.30
Presented Recommended RVU: 1.30
RUC Recommended RVU: 1.80

Global Period: 000

CPT Descriptor: Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter 1.1 to 2.0 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A 40 year old female presents for the removal of an atypical pigmented lesion on her cheek with a diameter 1.6cm. The lesion warrants complete removal for thorough pathologic evaluation.

Percentage of Survey Respondents who found Vignette to be Typical: 84%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: Positioning: Based upon lesion location and the technical detail required of the procedure, the patient is positioned for maximum flexibility for the surgeon while maintaining patient comfort. Records are checked to confirm patient, procedure and site. A photograph of the lesion is taken, printed and scanned/inserted into the patient's chart. The area is prepped, anaesthetized and draped. Anesthesia is injected in both subcutaneous and dermal compartments so that it results in a "raising" of the lesion to facilitate appropriate dermal depth removal.

Description of Intra-Service Work: Based on lesion type, size, and skin location, relaxed skin tension lines are marked. The dermal thickness in the location is evaluated, and then a margin between 2 to 5 mm is delineated with a surgical marker. The outline of the mark is scored using a scalpel. Starting at one end of the lesion the dermis is incised at anywhere from a 30 to 60 degree angle, to coincide with the leading edge of the skin lesion and to ensure that the path of removal is fully under the lesion yet still in the dermis. Hemostasis is achieved as needed, usually with pressure or topical application of aluminum chloride. The angle of dissection is then straightened to run parallel to the axis of the lesion, while remaining in the dermis. The shave proceeds forward following the pre-determined marked outline. As the dissection proceeds, the lesion is retracted as needed. This is accomplished by the placement of an initial suture to mark a border or retraction hooks or non-crushing forceps. The suture location is documented. As the midpoint is reached the dermal depth is checked to ensure that the fat is not penetrated and that the lesion appears in the entirety of the removed sample. Following the outline and maintaining a 30 to 60% transverse exit angle the lesion is removed. Additional hemostasis is achieved as above. Should further hemostasis need to be achieved, a fast-absorbing suture ligature or electrocautery can be utilized.

Description of Post-Service Work: The treatment site is monitored for delayed bleeding. An appropriate dressing for location and size is chosen (larger lesions might require Duoderm or some other flexible temporary skin substitute) and applied. Side effects, including pain, infection, oozing, and scaring are once again discussed with the patient, and the patient is discharged

with appropriate analgesics and wound care instructions. The specimen is sent to pathology with a request for thorough examination.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 68 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. Further, the CP recommends that 6 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

The CP reviewed the surveyed code in comparison to the key reference code 12013 (Work RVU=1.22) and noted that the surveyed code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code. Further, the CP noted that the total service time for the surveyed code exceeds the total service time for the reference code, 43 minutes and 27 minutes.

In addition, the CP compared the surveyed code to MPC code 11755 (work RVU=1.31). The CP noted that the 11755 has 55 minutes of total service time and the surveyed code has 41 minutes of total service time.

		Pre	Intra	Post	Total	RVU
MPC	11755	15	25	15	55	1.31
SVY	11312	6	30	5	41	1.80
K-Ref	12013	7	15	5	27	1.22

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 11312

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastics & Reconstructive Surgery How often? Rarely

Specialty Family Practice How often? Rarely

Estimate the number of times this service might be provided nationally in a one-year period? 157848
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimate 3X Medicare Utilization

Specialty Dermatology Frequency 121543 Percentage 77.00 %

Specialty Plastics & Reconstructive Surgery Frequency 10497 Percentage 6.65 %

Specialty Family Practice PAs etc Frequency 25809 Percentage 16.35 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 52,616 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Dermatology Frequency 40515 Percentage 77.00 %

Specialty Plastics Frequency 3499 Percentage 6.65 %

Specialty Family Practice, PAs etc Frequency 8603 Percentage 16.35 %

Do many physicians perform this service across the United States? Yes

---

Professional Liability Insurance Information (PLI)

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 11312

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:11313 Tracking Number Original Specialty Recommended RVU: 1.68
Presented Recommended RVU: 1.68
Global Period: 000 RUC Recommended RVU: 2.00

CPT Descriptor: Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter over 2.0 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A 40 year old female presents for the removal of an atypical pigmented lesion on her cheek with a diameter of 2.3cm. The lesion warrants complete removal for thorough pathologic evaluation.

Percentage of Survey Respondents who found Vignette to be Typical: 81%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: Positioning: Based upon lesion location and the technical detail required of the procedure, the patient is positioned for maximum flexibility for the surgeon while maintaining patient comfort. Records are checked to confirm patient, procedure and site. A photograph of the lesion is taken, printed and scanned/inserted into the patient's chart. The area is prepped, anaesthetized and draped. Anesthesia is injected in both subcutaneous and dermal compartments so that it results in a "raising" of the lesion to facilitate appropriate dermal depth removal.

Description of Intra-Service Work: Based on lesion type, size, and skin location, relaxed skin tension lines are marked. The dermal thickness in the location is evaluated, and then a margin between 2 to 5 mm is delineated with a surgical marker. The outline of the mark is scored using a scalpel. Starting at one end of the lesion the dermis is incised at anywhere from a 30 to 60 degree angle, to coincide with the leading edge of the skin lesion and to ensure that the path of removal is fully under the lesion yet still in the dermis. Hemostasis is achieved as needed, usually with pressure or topical application of aluminum chloride. The angle of dissection is then straightened to run parallel to the axis of the lesion, while remaining in the dermis. The shave proceeds forward following the pre-determined marked outline. As the dissection proceeds, the lesion is retracted as needed. This is accomplished by the placement of an initial suture to mark a border or retraction hooks or non-crushing forceps. The suture location is documented. As the midpoint is reached the dermal depth is checked to ensure that the fat is not penetrated and that the lesion appears in the entirety of the removed sample. Following the outline and maintaining a 30 to 60% transverse exit angle the lesion is removed. Additional hemostasis is achieved as above. Should further hemostasis need to be achieved, a fast-absorbing suture ligature or electrocautery can be utilized.

Description of Post-Service Work: The treatment site is monitored for delayed bleeding. An appropriate dressing for location and size is chosen (larger lesions might require Duoderm or some other flexible temporary skin substitute) and applied. Side effects, including pain, infection, oozing, and scaring are once again discussed with the patient, and the patient is discharged

with appropriate analgesics and wound care instructions. The specimen is sent to pathology with a request for thorough examination.

Median Immediate Post-service Time	5.00	5.00	
Median Critical Care Time	0.0	0.00	
Median Other Hospital Visit Time	0.0	0.00	
Median Discharge Day Management Time	0.0	0.00	
Median Office Visit Time	0.0	0.00	
Prolonged Services Time	0.0	0.00	
Median Subsequent Observation Care Time	0.0	0.00	
Median Total Time	**46.00**	**27.00**	

Other time if appropriate		

INTENSITY/COMPLEXITY MEASURES (Mean)		(of those that selected Key Reference code)
Mental Effort and Judgment (Mean)		
The number of possible diagnosis and/or the number of management options that must be considered	4.07	3.14
The amount and/or complexity of medical records, diagnostic tests, and/or other information that must be reviewed and analyzed	3.73	2.91
Urgency of medical decision making	3.86	3.14
Technical Skill/Physical Effort (Mean)		
Technical skill required	4.26	3.48
Physical effort required	3.85	3.08
Psychological Stress (Mean)		
The risk of significant complications, morbidity and/or mortality	4.05	3.20
Outcome depends on the skill and judgment of physician	4.17	3.42
Estimated risk of malpractice suit with poor outcome	3.98	3.26

INTENSITY/COMPLEXITY MEASURES	CPT Code	Reference Service 1
Time Segments (Mean)		
Pre-Service intensity/complexity	3.74	2.94
Intra-Service intensity/complexity	4.28	3.41
Post-Service intensity/complexity	3.87	3.07

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) has conducted a random survey of this code. Using the member database we identified both surgical and non-surgical members on the assumption that both surgical and general dermatologists would have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of members.

The AAD Consensus Panel (CP) reviewed the survey data from 68 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made based on the fact that this service is typically performed with an E&M service. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 5 minutes evaluation, 3 minutes positioning. Further, the CP recommends that 7 minutes be removed from the post service time period, to make consistent with other similar surgical procedures.

The CP reviewed the surveyed code in comparison to the key reference code 12013 (Work RVU=1.22) and noted that the surveyed code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code. Further, the CP noted that the total service time for the surveyed code exceeds the total service time for the reference code, 46 minutes and 27 minutes.

In addition, the CP compared the surveyed code to MPC code 64449 (work RVU=1.81). The CP noted that the 64449 has 60 minutes of total service time and the surveyed code has 46 minutes of total service time.

		Pre	Intra	Post	Total	RVU
MPC	64449	29	20	11	60	1.81

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   ☐ Multiple codes are used to maintain consistency with similar codes.
   ☐ Historical precedents.
   ☒ Other reason (please explain) Several of the shave codes are performed over 50% of the time with an evaluation and management service. To be consistent, it was the judgment of the CP that the entire family should be treated as if it was billed with an E&M, to maintain relativity across of the family. Thus, modifications were made to the pre-service time package extracting time to account for this type of reporting.

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 11313

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastic & REconstructive Surgery How often? Rarely

Specialty Family Practice How often? Rarely

Estimate the number of times this service might be provided nationally in a one-year period? 21678
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Dermatology Frequency 15171 Percentage 69.98 %

Specialty Plastics Frequency 1821 Percentage 8.40 %

Specialty Family Practice, Gen Surg etc Frequency 4687 Percentage 21.62 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 7,226 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Dermatology Frequency 5057 Percentage 69.98 %

Specialty Plastics Frequency 607 Percentage 8.40 %

Specialty Family Practice, Gen Surg etc Frequency 1562 Percentage 21.61 %

Do many physicians perform this service across the United States? Yes

Professional Liability Insurance Information (PLI)

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 11313

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

Compelling Evidence: Shave Codes

The American Academy of Dermatology (AAD) would like to submit the following compelling evidence for the shave codes. The AAD contends that:

Evidence that incorrect assumptions were made in the previous valuation of the service, as documented, ***such as****: a misleading vignette, survey and/or flawed crosswalk assumptions in a previous evaluation*

- The whole family of shave codes was previously reviewed by the RUC, but never surveyed and the results appeared in HCFA's December 2, 1993 final rule. At the time HCFA decided that the shave excision codes should be valued at 60% of the other excision codes, the 11400 series.

- The original RUC recommendation to HCFA was that "the shave codes should be valued at 80% of the other excision codes. The current values are already below what the RUC recommended. Therefore, the current values should be maintained." Both of these percentages were arbitrarily selected.

The AAD contends that this mechanism for valuation is **not** valid as it is not based on survey data or careful comparative relativity to any codes within the Fee Schedule. Therefore, relativity to other codes was not established by any recognized RUC standard.

- Since that time the excision codes have been redefined to INCLUDE the margins, using the phrase "excised diameter". There was no corresponding change in the shave codes values to reflect the shift in the definition: shave remained the lesion size, while the excision codes, which they were valued upon, shifted upwards. This shift passed budget neutrality according to the Medicare numbers in the RUC dbase, and was approved by the RUC.

- In addition, since there was never a breakout of times into pre, intra and post the RUC asked the Specialty society to do that, and a consensus panel suggested times. Please note that these time breakout were not derived from any survey. These times were approved by the RUC.

Based on this valuation history, the AAD contends that there is compelling evidence that incorrect assumptions were made in the previous valuation of these services. The specialty respectfully recommends that the RUC accept the survey value work RVUs (at the 25th percentile).

Practice Expense Summary of Recommendation
Non Facility Direct Inputs

CPT Long Descriptor:

11300 Shaving of epidermal or dermal lesion, single lesion, trunk, arms or legs; lesion diameter 0.5 cm or less

11301 Shaving of epidermal or dermal lesion, single lesion, trunk, arms or legs; lesion diameter 0.6 to 1.0 cm

11302 Shaving of epidermal or dermal lesion, single lesion, trunk, arms or legs; lesion diameter 1.1 to 2.0 cm

11303 Shaving of epidermal or dermal lesion, single lesion, trunk, arms or legs; lesion diameter over 2.0 cm

11305 Shaving of epidermal or dermal lesion, single lesion, scalp, neck, hands, feet, genitalia; lesion diameter 0.5 cm or less

11306 Shaving of epidermal or dermal lesion, single lesion, scalp, neck, hands, feet, genitalia; lesion diameter 0.6 to 1.0 cm

11307 Shaving of epidermal or dermal lesion, single lesion, scalp, neck, hands, feet, genitalia; lesion diameter 1.1 to 2.0 cm

11308 Shaving of epidermal or dermal lesion, single lesion, scalp, neck, hands, feet, genitalia; lesion diameter over 2.0 cm

11310 Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter 0.5 cm or less

11311 Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter 0.6 to 1.0 cm

11312 Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter 1.1 to 2.0 cm

11313 Shaving of epidermal or dermal lesion, single lesion, face, ears, eyelids, nose, lips, mucous membrane; lesion diameter over 2.0 cm

Global Period: **000** Meeting Date: **April 2012**

CPT Code: 11300; 11301; 11302; 11303; 11305; 11306; 11307; 11308; 11310; 11311; 11312; 11313

Specialty Society('s): American Academy of Dermatology

Please provide a brief description of the process used to develop your recommendation and the composition of your Specialty Society Practice Expense Committee:

The AAD RB/RVS committee has reviewed the RUC approved PE direct inputs for these codes as well as determined from industry data that there are no significant additions or changes to these inputs. The AAD Coding & Reimbursement Task Force as well as the RUC advisors for AAD, ASDS, ACMS and SID serve on the AAD RB/RVS committee.

If you have provided any comparison practice expense inputs on your spreadsheet, please provide a rationale for the selection of codes. Comparison Code Rationale:

Please describe in detail the clinical activities of your staff:

Please see PE Direct input spreadsheet.

Pre-Service Clinical Labor Activities:

Intra-Service Clinical Labor Activities:

Post-Service Clinical Labor Activities:

AMA/Specialty Society RVS Update RUC Summary of Recommendations
CMS Request - NPRM for 2012

April 2012

Complex Wound Repair

In April 2011, the RUC identified codes 13131 and 13152 as part of the Harvard Valued – Utilization Over 30,000 screen for survey at the September 2011 meeting. CPT codes 13100 and 13101 were reviewed as part of the 4th Five-Year Review. However, in the June 6, 2011 *Proposed Rule* for the 4th Five-Year Review of the RBRVS, CMS requested that the RUC review the entire family of complex wound repair codes to ensure consistency and appropriate gradation of work value. The RUC recommended that the specialty society re-survey codes 13100-13152 for the April 2012 RUC meeting.

13100 Repair, complex, trunk; 1.1 cm to 2.5 cm
The RUC reviewed the survey results from 101 dermatologists and plastic surgeons for 13100 and recommends the survey 25th percentile work RVU of 3.00, which is lower than the current value. The RUC compared 13100, with 32 minutes of intra-service time to CPT codes 11603 *Excision, malignant lesion including margins, trunk, arms, or legs; excised diameter 2.1 to 3.0 cm* (work RVU = 2.82 and intra-time = 30 minutes) and 11444 *Excision, other benign lesion including margins, except skin tag (unless listed elsewhere), face, ears, eyelids, nose, lips, mucous membrane; excised diameter 3.1 to 4.0 cm* (work RVU = 3.19 and intra-service time = 40 minutes), and determined that using magnitude estimation, the work required to perform 13100 is appropriately placed between these two services. The RUC determined that CPT code 13100 requires more physician time to perform to apply anesthesia to a larger area using a regional block, to undermine tissue and requires more cosmetic detail to repair compared to excision code 11603. **The RUC recommends a work RVU of 3.00 for CPT code 13100.**

13101 Repair, complex, trunk; 2.6 cm to 7.5 cm
The RUC reviewed the survey results from 95 dermatologists and plastic surgeons for 13101 and recommends the survey 25th percentile work RVU of 3.50, which is lower than the current value. The RUC determined that survey 25th percentile appropriately places this service in the proper rank order relative to code 13100 which requires 32 minutes of intra-service time compared to 45 minutes of intra-service time required to perform 13101, as well as accounts for the larger area repaired. For additional support the RUC compared 13101 to key reference service 12032 *Repair, intermediate, wounds of scalp, axillae, trunk and/or extremities (excluding hands and feet); 2.6 cm to 7.5 cm* (work RVU = 2.52 and 30 minutes intra-service time) and MPC code 11644 *Excision, malignant lesion including margins, face, ears, eyelids, nose, lips; excised diameter 3.1 to 4.0 cm* (work RVU = 4.34 and 45 minutes intra-service time) and determined the physician work and time required to perform 13101 appropriately places this service in the proper rank order. **The RUC recommends a work RVU of 3.50 for CPT code 13101.**

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

13102 Repair, complex, trunk; each additional 5 cm or less (List separately in addition to code for primary procedure)
The RUC reviewed the survey results from 128 dermatologists and plastic surgeons for 13102 and recommends the survey median intra-service time of 30 minutes and that the current work RVU of 1.24 be maintained. The RUC compared 13102 to key reference code 14302 *Adjacent tissue transfer or rearrangement, any area; each additional 30.0 sq cm, or part thereof (List separately in addition to code for primary procedure)* (work RVU = 3.73 and 40 minutes intra-service time) and MPC code 93563 *Injection procedure during cardiac catheterization including imaging supervision, interpretation, and report; for selective coronary angiography during congenital heart catheterization (List separately in addition to code for primary procedure)* (work RVU = 1.11 and 25 minutes intra-service time) and determined that a work RVU of 1.24 appropriately places this service in the proper rank order. **The RUC recommends a work RVU of 1.24 for CPT code 13102.**

13120 Repair, complex, scalp, arms, and/or legs; 1.1 cm to 2.5 cm
The RUC reviewed the survey results from 82 dermatologists and plastic surgeons for 13120 and recommends the survey median intra-service time of 35 minutes and survey 25th percentile work RVU of 3.23. The RUC compared 13120 to the recommended value for 13100 *Repair, complex, trunk; 1.1 cm to 2.5 cm* (recommended work RVU = 3.00 and 32 minutes intra-service time) and determined that 13120 requires slightly more intra-service time and it is more intense and complex to repair these body regions versus repairing a wound of the same size on the trunk. The RUC also compared 13120 to key reference service 12031 *Repair, intermediate, wounds of scalp, axillae, trunk and/or extremities (excluding hands and feet); 2.5 cm or less* (work RVU = 2.00 and 20 minutes intra-service time) and MPC code 11643 *Excision, malignant lesion including margins, face, ears, eyelids, nose, lips; excised diameter 2.1 to 3.0 cm* (work RVU = 3.42 and 30 minutes intra-service time) and determined that a work RVU of 3.23 appropriately places this service in the proper rank order. **The RUC recommends 3.23 work RVUs for CPT code 13120.**

13121 Repair, complex, scalp, arms, and/or legs; 2.6 cm to 7.5 cm
The RUC reviewed the survey results from 94 dermatologists and plastic surgeons for 13121 and recommends the survey intra-service time of 45 minutes and the survey 25th percentile work RVU of 4.00. The specialty society recommended and the RUC agreed that the intra-service time is 45 minutes and 1-99212 Office visit is typically required, not two as is currently included in this global period. Therefore, the decrease in work RVUs from the current work RVU of 4.42 is appropriate. The RUC also compared 13121 to CPT code 11010 *Debridement including removal of foreign material at the site of an open fracture and/or an open dislocation (eg, excisional debridement); skin and subcutaneous tissues* (work RVU = 4.19 and 50 minutes intra-service time) and MPC code 11644 Excision, malignant lesion including margins, face, ears, eyelids, nose, lips; excised diameter 3.1 to 4.0 cm (work RVU = 4.34 and 45 minutes intra-service time) and determined that a work RVU of 4.00 places this service in the proper rank order. **The RUC recommends a work RVU of 4.00 for CPT code 13121.**

13122 Repair, complex, scalp, arms, and/or legs; each additional 5 cm or less (List separately in addition to code for primary procedure)
The RUC reviewed the survey results from 96 dermatologists and plastic surgeons for 13122 and recommends the survey median intra-service time of 30 minutes and that the current work RVU of 1.44 be maintained. The RUC compared 13122 to the recommended value for 13102 *Repair, complex, trunk; each additional 5 cm or less* (recommended work RVU = 1.24 and 30 minutes intra-service time) and determined that 13122 requires the same intra-service time, but is more intense and complex to repair these body regions versus repairing a wound of the same size on the

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

trunk. The RUC also compared 13122 to key reference service 14302 *Adjacent tissue transfer or rearrangement, any area; each additional 30.0 sq cm, or part thereof (List separately in addition to code for primary procedure)* (work RVU = 3.73) and 15121 *Split-thickness autograft, face, scalp, eyelids, mouth, neck, ears, orbits, genitalia, hands, feet, and/or multiple digits; each additional 100 sq cm, or each additional 1% of body area of infants and children, or part thereof (List separately in addition to code for primary procedure)* (work RVU = 2.00) and determined that the 13122 requires less physician work to perform. **The RUC recommends a work RVU of 1.44 for CPT code 13122.**

13131 Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 1.1 cm to 2.5 cm
The RUC reviewed the survey results from 87 dermatologists and plastic surgeons for 13131 and recommends the survey intra-service time of 45 minutes and the survey 25th percentile work RVU of 3.73. The RUC compared 13131 to the recommended value for 13120 *Repair, complex, scalp, arms, and/or legs; 1.1 cm to 2.5 cm* (recommended work RVU = 3.23 and 35 minutes intra-service time) and determined that 13131 requires 10 more intra-service time and it is more intense and complex to repair these body regions versus repairing a wound of the same size on the scalp, arms and/or legs. The RUC also compared 13131 to MPC code 11644 *Excision, malignant lesion including margins, face, ears, eyelids, nose, lips; excised diameter 3.1 to 4.0 cm* (work RVU = 4.34 and intra-service time = 45 minutes) and determined that a work RVU of 3.73 places this service in the proper rank order. **The RUC recommends 3.73 work RVUs for CPT code 13131.**

13132 Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 2.6 cm to 7.5 cm
The RUC reviewed the survey results from 115 dermatologists and plastic surgeons for 13132 and recommends the survey 25th percentile work RVU of 4.78. The specialty society recommended and the RUC agreed that the intra-service time is 50 minutes and 1-99212 Office visit is typically required, not two as is currently included in this global period. Therefore, the decrease in work RVUs from the current work RVU of 6.58 is appropriate. The RUC also compared 13132 to similar service 11446 *Excision, other benign lesion including margins, except skin tag (unless listed elsewhere), face, ears, eyelids, nose, lips, mucous membrane; excised diameter over 4.0 cm* (work RVU = 4.80 and 60 minutes intra-service time) and determined this a work RVU of 4.78 places this service in the proper rank order. **The RUC recommends a work RVU of 4.78 for CPT code 13132.**

13133 Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; each additional 5 cm or less (List separately in addition to code for primary procedure)
The RUC reviewed the survey results from 93 dermatologists and plastic surgeons for 13133 and recommends the survey median intra-service time of 35 minutes and that the survey 25th percentile work RVU of 2.19. The RUC compared 13133 to the recommended value for 13122 *Repair, complex, scalp, arms, and/or legs; each additional 5 cm or less* (recommended work RVU = 1.44 and 30 minutes intra-service time) and determined that 13133 requires more physician time to perform and is more intense and complex to repair these body regions versus repairing a wound of the same size on the scalp, arms and/or legs. The RUC also compared 13133 to 15121 *Split-thickness autograft, face, scalp, eyelids, mouth, neck, ears, orbits, genitalia, hands, feet, and/or multiple digits; each additional 100 sq cm, or each additional 1% of body area of infants and children, or part thereof (List separately in addition to code for primary procedure)* (work RVU = 2.00 and 30 minutes intra-service time) and determined that 13133 requires more physician work and time to perform. **The RUC recommends a work RVU of 2.19 for CPT code 13133.**

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

13150 Repair, complex, eyelids, nose, ears and/or lips; 1.0 cm or less
The RUC reveiwed the speiclaties request to delete CPT 13150. The RUC determined that the 1.0 cm or less size of this repair makes it a medically unlikely complex repair due to the small size of the repair. The specialty will submit a CPT proposal requesting deletion of this code for consideration at the October 2012 CPT meeting. **The RUC recommends deletion of CPT code 13150.**

13151 Repair, complex, eyelids, nose, ears and/or lips; 1.1 cm to 2.5 cm
The RUC reviewed the survey results from 144 dermatologists and plastic surgeons for CPT 13151 and determined that the survey 25th percentile work RVU of 3.50 was too low and would cause a rank order anomaly compared to less intense code 13131 *Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 1.1 cm to 2.5 cm* (recommended work RVU = 3.73). CPT code 13151 is more intense and complex to perform than 13131. CPT code 13151 has a higher risk of complication, requires finer smaller sutures in a delicate area, is more challenging to repair with underlying tissue planes and adjacent structures, has a more cosmetic impact and involves repair on mobile areas. Therefore, the RUC recommends a direct crosswalk to CPT code 11644 *Excision, malignant lesion including margins, face, ears, eyelids, nose, lips; excised diameter 3.1 to 4.0 cm* (work RVU = 4.34 and intra-service time = 45 minutes) in order to maintain rank order among this family of services. **The RUC recommends a work RVU of 4.34 for CPT code 13151.**

13152 Repair, complex, eyelids, nose, ears and/or lips; 2.6 cm to 7.5 cm
The RUC reviewed the survey results from 107 dermatologists and plastic surgeons for CPT 13152 and determined that the survey 25th percentile work RVU of 4.90 was too low and would cause a rank order anomaly compared to less intense code 13132 *Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 2.6 cm to 7.5 cm* (recommended work RVU = 4.78). CPT code 13152 is more intense and complex to perform than 13132. CPT code 13152 has a higher risk of complication, requires finer smaller sutures in a delicate area, is more challenging to repair with underlying tissue planes and adjacent structures, has a more cosmetic impact and involves repair on mobile areas. Therefore, the RUC recommends a direct crosswalk to CPT code 36571 *Insertion of peripherally inserted central venous access device, with subcutaneous port; age 5 years or older* (work RVU = 5.34 and intra-service time = 50 minutes) in order to maintain rank order among this family of services. **The RUC recommends a work RVU of 5.34 for CPT code 13152.**

13153 Repair, complex, eyelids, nose, ears and/or lips; each additional 5 cm or less (List separately in addition to code for primary procedure)
The RUC reviewed the survey results from 92 dermatologists and plastic surgeons for CPT 13153 and determined that the survey 25th percentile work RVU of 2.20 too low and would cause a rank order anomaly compared 13133 *Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; each additional 5 cm or less* (recommended work RVU = 2.19 and intra-service time 35 minutes), which is less intense and requires 10 minutes less intra-service time to perform. The RUC compared 13153 to key reference service 14302 *Adjacent tissue transfer or rearrangement, any area; each additional 30.0 sq cm, or part thereof (List separately in addition to code for primary procedure)* (work RVU = 3.73 and 40 minutes intra-service time) and similar service 22116 *Partial excision of vertebral body, for intrinsic bony lesion, without*

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

decompression of spinal cord or nerve root(s), single vertebral segment; each additional vertebral segment (List separately in addition to code for primary procedure) (work RVU = 2.32 and 45 minutes intra-service time) and determined that a work RVU of 2.38 places this service in the proper rank order. **The RUC recommends the survey median and current RVU of 2.38 for CPT code 13153.**

CPT Code	Pre-Eval	Pre-Posit	Pre-SDW	Intra	Imm Post	Survey Value	Rec wRVU

Work Neutrality
The RUC's recommendation for this family of codes will result in an overall work savings that should be redistributed back to the Medicare conversion factor.

Practice Expense
The RUC reviewed and approved the direct practice expense inputs with modifications as recommended by the Practice Expense Subcommittee.

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

CPT Code (•New)	CPT Descriptor	Global Period	Work RVU Recommendation

Barbara Levy, M.D.
Chair, Relative Value Scale Update Committee
American Medical Association
515 North State Street
Chicago, IL 60654

RE: Tab 38: Complex Wound Repair; Deletion of CPT 13150

Dear Dr. Levy:

Please accept this letter on behalf of the American Academy of Dermatology (AAD), the American Academy of Otolaryngology – Head and Neck Surgery (AAO-HNS), and the American Society of Plastic Surgery (ASPS). Together, our societies surveyed the family of complex wound repair CPT codes; 13100 – 13153, representing Tab 38 for the upcoming April Relative Update Committee (RUC) meeting.

We are writing to outline our request, presented to the Research Sub-committee during the February 27th call, to delete CPT 13150 *Repair, complex, eyelids, nose, ears and/or lips; 1.0 cm or less.* Our rationale for this request is based upon our belief that the 1.0 cm or less size of this repair makes it a medically unlikely complex repair due to the small size of the repair. As stated on the call, our societies intend to submit a CPT proposal requesting deletion of this code by the July 2012 deadline for consideration at the October 2012 CPT meeting. Given that the Research Sub-committee was receptive to this proposal, we respectfully request that the RUC panel also approve our request for deletion of CPT 13150.

Thank you in advance for your consideration. We urge you to contact us with any questions or concerns regarding this proposal. You may reach the relevant Society staff at: Norma Border, AAD, at nborder@aad.org or 847-240-1814; Melanie Dolak, ASPS, at mdolak@plasticsurgery.org or 847-228-3317; or Jenna Minton, AAO-HNS, at jminton@entnet.org or 703.535.3725.

Sincerely,

Brett Coldiron, MD
AAD RUC Advisor

Wayne Koch, MD
AAO-HNS RUC Advisor

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13100 Tracking Number

Original Specialty Recommended RVU: 3.17
Presented Recommended RVU: 3.17
RUC Recommended RVU: 3.00

Global Period: 010

CPT Descriptor: Repair, complex, trunk; 1.1 cm to 2.5 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the back. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 2.0 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 94%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 100%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Further anesthesia is provided as indicated. The repair is incised to or through fascia and wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

Median Immediate Post-service Time	10.00	7.00	
Median Critical Care Time	0.0	0.00	
Median Other Hospital Visit Time	0.0	0.00	
Median Discharge Day Management Time	0.0	0.00	
Median Office Visit Time	16.0	16.00	
Prolonged Services Time	0.0	0.00	
Median Subsequent Observation Care Time	0.0	0.00	
Median Total Time	**78.00**	***56.00***	

Other time if appropriate		

INTENSITY/COMPLEXITY MEASURES (Mean)		(of those that selected Key Reference code)
Mental Effort and Judgment (Mean)		
The number of possible diagnosis and/or the number of management options that must be considered	4.00	2.96
The amount and/or complexity of medical records, diagnostic tests, and/or other information that must be reviewed and analyzed	3.63	2.96
Urgency of medical decision making	3.88	3.03
Technical Skill/Physical Effort (Mean)		
Technical skill required	4.51	3.22
Physical effort required	4.22	3.07
Psychological Stress (Mean)		
The risk of significant complications, morbidity and/or mortality	3.96	3.04
Outcome depends on the skill and judgment of physician	4.29	3.37
Estimated risk of malpractice suit with poor outcome	3.40	2.85

INTENSITY/COMPLEXITY MEASURES	CPT Code	Reference Service 1
Time Segments (Mean)		
Pre-Service intensity/complexity	3.63	2.81
Intra-Service intensity/complexity	4.22	3.18
Post-Service intensity/complexity	3.59	2.815

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) conducted a random survey of these codes. Using the member database we identified surgical subspecialty members who would likely have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of surgeons.

		Pre	Intra	Post	Post-op	Total	RVU

MPC	11444	20	40	10	16	86	3.19
SVY	13100	20	32	10	16	78	3.17
K-REF	12031	13	20	7	16	56	2.00

Based on these comparisons, the CP recommends 3.17 work RVUs, the current value for 13100.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13100

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastic Surgery How often? Commonly

Specialty How often?

Estimate the number of times this service might be provided nationally in a one-year period? 15525
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Three times Medicare utilization estimate

Specialty Dermatology Frequency 8862 Percentage 57.08 %

Specialty Plastic Surgery Frequency 3153 Percentage 20.30 %

Specialty Gen Surg, Fam Pract, Other Frequency 3510 Percentage 22.60 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 5,175 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. RUC Database

Specialty Dermatology Frequency 2954 Percentage 57.08 %

Specialty Plastic Surgery Frequency 1051 Percentage 20.30 %

Specialty Gen Surg, Fam Pract, Other Frequency 1170 Percentage 22.60 %

Do many physicians perform this service across the United States? Yes

---

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 13100

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13101 Tracking Number

Original Specialty Recommended RVU: 3.96
Presented Recommended RVU: 3.96
RUC Recommended RVU: 3.50

Global Period: 010

CPT Descriptor: Repair, complex, trunk; 2.6 cm to 7.5 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the back. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 6.0 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 93%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 99%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Further anesthesia is provided as indicated. The repair is incised to or through fascia and wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

CPT Code:13102 Tracking Number Original Specialty Recommended RVU: **1.24**
Presented Recommended RVU: **1.24**
Global Period: ZZZ RUC Recommended RVU: **1.24**

CPT Descriptor: Repair, complex, trunk; each additional 5 cm or less (List separately in addition to code for primary procedure)

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the back. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 10.0 cm. Please note that this is an add-on code. The first 7.5 cm repaired is reported separately with code 13101. When completing this survey, only consider the additional work for the additional 2.5 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 97%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: N/A - pre-service work included in global of primary procedure.

Description of Intra-Service Work: Intra-service work includes ongoing complex repair of wound length after the first 7.5 cm. This will involve additonal injection of local anesthetic, additional sharp incision, additional wide undermining, additional hemostasis by electrocautery and ligature, and additional multilayered suturing.

Description of Post-Service Work: N/A - Add on code Comment: In general no post time is applied to add on codes. However, in the extent of extensive wounds and/or lacerations requiring lengthy suture lines and/or mutliple suture lines additional provider time will be required to counsel the patient, review wound care, and see the patient durning the postoperative global period.

Intra-Service intensity/complexity	3.63	4.11
Post-Service intensity/complexity	2.79	3.42

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) and the American Society of Plastic Surgeons have each conducted a random survey of these codes. Using their respective member databases, they identified those surgical subspecialty members

who would likely have performed this procedure within the last twelve months. AAD and ASPS distributed the survey(s) directly to the identified random sample of surgeons.

		Pre	Intra	Post	Post-op	Total	RVU
K-Ref	14302	0	40	0	0	40	3.73
SVY	13102	0	30	0	0	30	1.24
Ref	93563	0	25	0	0	25	1.11

Based on these comparisons, the CP recommends 1.24 work RVUs, the current value for 13102, a value significantly below the 25th percentile.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☒ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario. 13100 &13101 - Base codes

SUMMARY OF RECOMMENDATION

CPT Code:13120 Tracking Number Original Specialty Recommended RVU: 3.35
Presented Recommended RVU: 3.35
Global Period: 010 RUC Recommended RVU: 3.23

CPT Descriptor: Repair, complex, scalp, arms, and/or legs; 1.1 cm to 2.5 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the scalp. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 2.0 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 94%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 100%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Further anesthesia is provided as indicated. The repair is incised to or through fascia and wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) conducted a random survey of these codes. Using the member database we identified surgical subspecialty members who would likely have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of surgeons.

The AAD Consensus Panel (CP) reviewed the survey data from 101 dermatologists and determined that the pre-service time package that should be selected is package 6. Modifications to the pre-service time package are made to better

reflect pre-service time activities. Further modifications were made to the positioning time as specialized patient positioning is required for the success of the procedure. Both of these modifications are supported by the survey data. Therefore, the CP recommends pre-service time of 14 minutes evaluation, 5 minutes positioning and 5 minutes of scrub dress and wait.

The CP reviewed the surveyed code in comparison to the key reference code 12031 (Work RVU=2.00) and noted that the surveyed code has significantly more intra-service time associated with it as compared to the reference code, 35 minutes and 20 minutes. Further, the surveyed code requires significantly more mental effort and judgment, technical skill, physical effort and overall is a more intense service to perform in comparison to the reference code.

In addition, the CP compared the surveyed code to MPC code 11643 (work RVU=3.42). The CP noted that the 11643 has 93 minutes of total service time and the surveyed code has 86 minutes of total service time.

		Pre	Intra	Post	Post-Op	Total	RVU

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13121

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastic Surgery How often? Commonly

Specialty How often?

Estimate the number of times this service might be provided nationally in a one-year period? 291591
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Three times Medicare utilization

Specialty Dermatology Frequency 226830 Percentage 77.79 %

Specialty Plastic Surgery Frequency 29889 Percentage 10.25 %

Specialty Gen Surg, Fam Pract, etc Frequency 34872 Percentage 11.95 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 97,197 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. RUC Database

Specialty Dermatology Frequency 75610 Percentage 77.79 %

Specialty Plastic Surgery Frequency 9963 Percentage 10.25 %

Specialty Gen Surg, Fam Pract, etc Frequency 11624 Percentage 11.95 %

Do many physicians perform this service across the United States? Yes

---

Professional Liability Insurance Information (PLI)

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 13121

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13122 Tracking Number Original Specialty Recommended RVU: **1.44**
Presented Recommended RVU: **1.44**
Global Period: ZZZ RUC Recommended RVU: **1.44**

CPT Descriptor: Repair, complex, scalp, arms, and/or legs; each additional 5 cm or less (List separately in addition to code for primary procedure)

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the scalp. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 10.0 cm. Please note that this is an add-on code. The first 7.5 cm repaired is reported separately with code 13121. When completing this survey, only consider the additional work for the additional 2.5 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 92%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 100%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: N/A - pre-service work included in global of primary procedure.

Description of Intra-Service Work: Intra-service work includes ongoing complex repair of wound length after the first 7.5 cm. This will involve additonal injection of local anesthetic, additional sharp incision, additional wide undermining, additional hemostasis by electrocautery and ligature, and additional multilayered suturing.

Description of Post-Service Work: N/A - Add on code Comment: In general no post time is applied to add on codes. However, in the extent of extensive wounds and/or lacerations requiring lengthy suture lines and/or mutliple suture lines additional provider time will be required to counsel the patient, review wound care, and see the patient durning the postoperative global period.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13131 Tracking Number Original Specialty Recommended RVU: 3.83
Presented Recommended RVU: 3.83
Global Period: 010 RUC Recommended RVU: 3.73

CPT Descriptor: Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 1.1 cm to 2.5 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the forehead. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 2.0 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 97%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 100%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Closure is carefully planned along skin tension lines and in a manner to avoid tension on / alteration of free margins. Further anesthesia is provided as indicated. The repair is incised to or through fascia and the wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

Intra-Service intensity/complexity	4.28	3.57
Post-Service intensity/complexity	3.85	3.19

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) conducted a random survey of these codes. Using the member database we identified surgical subspecialty members who would likely have performed this procedure within the last twelve months. AAD distributed the survey(s) directly to the identified random sample of surgeons.

		Pre	Intra	Post	Post-Op	Total	RVU
MPC	11644	30	45	10	23	108	4.34
SVY	13131	20	45	15	16	96	3.73
K-REF	12054	20	50	10	16	96	3.50

Based on these comparisons, the CP recommends 3.83 work RVUs, the current work RVU for 13131.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13131

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastic Surgery How often? Commonly

Specialty How often?

Estimate the number of times this service might be provided nationally in a one-year period? 98631
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Three times Medicare utilization

Specialty Dermatology Frequency 71175 Percentage 72.16 %

Specialty Plastic Surgery Frequency 14382 Percentage 14.58 %

Specialty ENT, Fam Pract Frequency 13074 Percentage 13.25 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 32,877 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. RUC Database

Specialty Dermatology Frequency 23725 Percentage 72.16 %

Specialty Plastic Surgery Frequency 4794 Percentage 14.58 %

Specialty ENT, Fam Pract Frequency 4358 Percentage 13.25 %

Do many physicians perform this service across the United States? Yes

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13132 Tracking Number Original Specialty Recommended RVU: 6.00
Presented Recommended RVU: 6.00
Global Period: 010 RUC Recommended RVU: 4.78

CPT Descriptor: Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 2.6 cm to 7.5 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the forehead. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 6.0 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 92%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 8% , In the ASC 0%, In the office 92%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 8% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 3%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Closure is carefully planned along skin tension lines and in a manner to avoid tension on / alteration of free margins. Further anesthesia is provided as indicated. The repair is incised to or through fascia and the wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD), the American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS) and the American Society of Plastic Surgeons have each conducted a random survey of these codes. Using their respective member databases, they identified surgical subspecialty members who would likely have performed this procedure within the last twelve months. AAO-HNS queried this subset of their membership to determine if they had performed the procedure and were willing to participate in the survey.

AAD and ASPS distributed the survey(s) directly to the identified random sample of surgeons.

		Pre	Intra	Post	Post-Op	Total	RVU
MPC	38510	45	45	20	42	152	6.74
SVY	13132	25	50	15	16	108	4.78
K-REF	12054	20	50	10	16	96	3.50

Based on these comparisons, the CP recommends 6.00 work RVUs, the median which is significantly less than the current work RVU for 13132.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☒ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario. 17311 000 6.20 pre- 20 intra- 110 post- 8 Both codes are subject to the multiple procedure reduction.

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13132

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastic Surgery How often? Commonly

Specialty Otolaryngology How often? Sometimes

Estimate the number of times this service might be provided nationally in a one-year period? 564456
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Three times the Medicare Utilization

Specialty Dermatology Frequency 471267 Percentage 83.49 %

Specialty Plastic Surgery Frequency 48150 Percentage 8.53 %

Specialty Otolaryngology Frequency 17950 Percentage 3.18 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 188,152
If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. RUC Database

Specialty Dermatology	Frequency 157089	Percentage 83.49 %
Specialty Plastic Surgery	Frequency 16050	Percentage 8.53 %
Specialty Otolaryngology	Frequency 5983	Percentage 3.17 %

Do many physicians perform this service across the United States? Yes

Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: N/A - pre-service work included in global of primary procedure.

Description of Intra-Service Work: Intra-service work includes ongoing complex repair of wound length after the first 7.5 cm. This will involve additonal injection of local anesthetic, additional sharp incision, additional wide undermining, additional hemostasis by electrocautery and ligature, and additional multilayered suturing.

Description of Post-Service Work: N/A - Add on code Comment: In general no post time is applied to add on codes. However, in the extent of extensive wounds and/or lacerations requiring lengthy suture lines and/or mutliple suture lines additional provider time will be required to counsel the patient, review wound care, and see the patient durning the postoperative global period.

Intra-Service intensity/complexity	3.79	4.05
Post-Service intensity/complexity	3.21	3.53

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) and the American Society of Plastic Surgeons have each conducted a random survey of these codes. Using their respective member databases, they identified those surgical subspecialty

members who would likely have performed this procedure within the last twelve months. AAD and ASPS distributed the survey(s) directly to the identified random sample of surgeons.

		Pre	Intra	Post	Post-Op	Total	RVU
K-REF	14302		40			40	3.73
SVY	13133		35			35	2.19
Ref	93563		25			25	1.11

Based on these comparisons, the CP recommends 2.19 work RVUs, the 25th percentile which also is the current work RVU for 13133.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☒ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario. 13131 & 13132

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13133

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Plastic Surgery How often? Sometimes

Specialty Gen Surg, Otolaryngology etc How often? Rarely

Estimate the number of times this service might be provided nationally in a one-year period? 33066
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. 3X Medicare Utilization

Specialty Dermatology Frequency 18617 Percentage 56.30 %

Specialty Plastics Frequency 8168 Percentage 24.70 %

Specialty Gen Surg, Otolaryngology etc Frequency 6282 Percentage 18.99 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 11,022 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Dermatology Frequency 6206 Percentage 56.30 %

Specialty Plastic Surgery Frequency 2723 Percentage 24.70 %

Specialty Gen Surg, Otolaryngology etc Frequency 431 Percentage 3.91 %

Do many physicians perform this service across the United States? Yes

---

Professional Liability Insurance Information (PLI)

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13151 Tracking Number

Original Specialty Recommended RVU: 4.49
Presented Recommended RVU: 4.49
RUC Recommended RVU: 4.34

Global Period: 010

CPT Descriptor: Repair, complex, eyelids, nose, ears and/or lips; 1.1 cm to 2.5 cm

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the nose. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 2.0 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 91%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 30% , In the ASC 3%, In the office 67%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 23% , Overnight stay-less than 24 hours 2% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 10%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Closure is carefully planned along skin tension lines and in a manner to avoid tension on / alteration of free margins. Further anesthesia is provided as indicated. The repair is incised to or through fascia and the wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☒ Other reason (please explain) Repair of wound or excision

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario. AAD - 17311 Mohs micrographic technique, including removal of all gross tumor, surgical excision of tissue specimens, mapping, color coding of specimens, microscopic examination of specimens by the surgeon, and histopathologic preparation including routine stain(s) (eg, hematoxylin and eosin, toluidine blue), head, neck, hands, feet, genitalia, or any location with surgery directly involving muscle, cartilage, bone, tendon, major nerves, or vessels; first stage, up to 5 tissue blocks

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13151

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Otolaryngology How often? Sometimes

Specialty Plastic Surgery How often? Sometimes

Estimate the number of times this service might be provided nationally in a one-year period? 90921
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimate done 3X more than Medicare population

Specialty Dermatology Frequency 66500 Percentage 73.14 %

Specialty Plastics Frequency 14712 Percentage 16.18 %

Specialty Otolaryngology Frequency 6209 Percentage 6.82 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 30,307 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare Claims Data

Specialty Dermatology Frequency 22167 Percentage 73.14 %

Specialty Plastics Frequency 4904 Percentage 16.18 %

Specialty Otolaryngology Frequency 2069 Percentage 6.82 %

Do many physicians perform this service across the United States? Yes

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the nose. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 3.5 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 88%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 1% , In the ASC 3%, In the office 96%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 3%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 2%

Description of Pre-Service Work: The history and exam are reviewed. The procedure is explained to the patient / family. The risks and potential complications are reviewed. Communication with the referring physician is undertaken as indicated. Written consent is obtained. The patient is transferred to the operative table and is positioned for the procedure. The site is identified and a time out is performed. Photographs are obtained as indicated. The area is prepped and draped in the usual sterile fashion. Local anesthetic is administered. The provider scrubs and dons gown, mask, and sterile gloves. The instruments are examined. Suture is obtained and placed on the surgical tray.

Description of Intra-Service Work: The wound is examined with sterile gloves and appropriate closure direction is determined. The closure is drawn onto the skin with a sterile marking pen, thus delineating a fusiform closure. Closure is carefully planned along skin tension lines and in a manner to avoid tension on / alteration of free margins. Further anesthesia is provided as indicated. The repair is incised to or through fascia and the wound edges are freshened as needed. The wound is extensively undermined. Hemostasis is obtained with spot electrocautery and ligature as indicated. The wound is closed in a multilayered fashion including retention sutures and / or stents as indicated. Final hemostasis is verified. The closure is assessed for cosmesis.

Description of Post-Service Work: All sterile prep is removed with sterile saline or peroxide. The wound is dressed in the usual sterile fashion with petrolatum, non-stick gauze pad, absorbant gauze, and cloth tape. Postoperative wound care and activity restrictions are discussed with the patient and provided in writing. Orders for postoperative antibiotic and pain medication are written as appropriate. The operative report is either dictated or completed in the electronic medical record. Photos are obtained as indicated. The patient is examined within the first week for a wound check and again as needed throughout the 10-day global period. Sutures are generally removed at 7 to 10 days. Communication is provided verbally and/or in writing/electronically to the primary care or referring physician.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD), the American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS) and the American Society of Plastic Surgeons have each conducted a random survey of these codes. Using their respective member databases, they identified surgical subspecialty members who would likely have performed this procedure within the last twelve months. AAO-HNS queried this subset of their membership to determine if they had performed the procedure and were willing to participate in the survey. AAD and ASPS distributed the survey(s) directly to the identified random sample of surgeons.

		Pre	Intra	Post	Post-Op	Total	RVU
MPC	38510	45	45	20	42	152	6.74
SVY	13152	33	50	20	16	119	5.34
Ref	12054	20	50	10	16	96	3.50

Based on this comparison, the CP recommends 6.37 work RVUs, the current value for 13152.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☒ Other reason (please explain) Repair of wound or excision

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario. AAD - 17311 Mohs micrographic technique, including removal of all gross tumor, surgical excision of tissue specimens, mapping, color coding of specimens, microscopic examination of specimens by the surgeon, and histopathologic preparation including routine stain(s) (eg, hematoxylin and eosin, toluidine blue), head, neck, hands, feet, genitalia, or any location with surgery directly involving muscle, cartilage, bone, tendon, major nerves, or vessels; first stage, up to 5 tissue blocks. NOTE: Both subject to multiple procedure reduction

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13152

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Commonly

Specialty Otolaryngology How often? Sometimes

Specialty How often?

Estimate the number of times this service might be provided nationally in a one-year period? 130251
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimate done 3X more than Medicare population

Specialty Dermatology Frequency 99147 Percentage 76.11 %

Specialty Otolaryngology Frequency 5861 Percentage 4.49 %

Specialty Plastic Surgery Frequency 17910 Percentage 13.75 %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 43,417 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare claims data

Specialty Dermatology Frequency 32997 Percentage 76.00 %

Specialty Otolaryngology Frequency 1954 Percentage 4.50 %

Specialty Plastic Surgery Frequency 5970 Percentage 13.75 %

Do many physicians perform this service across the United States? Yes

---

Professional Liability Insurance Information (PLI)

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 13152

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
SUMMARY OF RECOMMENDATION

CPT Code:13153 Tracking Number Original Specialty Recommended RVU: 2.38
Presented Recommended RVU: 2.38
Global Period: ZZZ RUC Recommended RVU: 2.38

CPT Descriptor: Repair, complex, eyelids, nose, ears and/or lips; each additional 5 cm or less
(List separately in addition to code for primary procedure)

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: A patient presents with a skin and soft tissue defect on the nose and cheek. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 9.0 cm. Please note that this is an add-on code. The first 7.5 cm repaired is reported separately with code 13152. When completing this survey, only consider the additional work for the additional 1.5 cm.

Percentage of Survey Respondents who found Vignette to be Typical: 92%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 100%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Overnight stay-less than 24 hours 0% , Overnight stay-more than 24 hours 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Description of Pre-Service Work: N/A - pre-service work included in global of primary procedure.

Description of Intra-Service Work: Intra-service work includes assessment and complex repair of wound length after the first 2.5 cm. This may involve: additional draping; additional injection of local anesthetic; additional removal of wound debris; additional irrigation with sterile saline; additional suturing of ligated vessels; additional electrocauterization for hemostasis; additional repair of muscle(s) deep fascial layer(s); additional suturing of skin; and additional dresssing application.

Description of Post-Service Work: N/A - Add on code Comment: In general no post time is applied to add on codes. However, in the extent of extensive wounds and/or lacerations requiring lengthy suture lines and/or mutliple suture lines additional provider time will be required to counsel the patient, review wound care, and see the patient durning the postoperative global period.

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

The American Academy of Dermatology (AAD) and the American Society of Plastic Surgeons have each conducted a random survey of these codes. Using their respective member databases, they identified those surgical subspecialty members

who would likely have performed this procedure within the last twelve months. AAD and ASPS distributed the survey(s) directly to the identified random sample of surgeons.

After the surveys were completed, our consensus panel realized that the vignette for CPT 13153 has an error. The vignette reads: "A patient presents with a skin and soft tissue defect on the nose and cheek. To achieve tension free closure, extensive undermining is performed and appropriate sutures are placed. The final wound length is 9.0 cm. Please note that this is an add-on code. The first 7.5 cm repaired is reported separately with code 13152. When completing this survey, only consider the additional work for the additional 1.5 cm."

Repair of the cheek is not included in the CPT 13153 descriptor. Thus, the vignette should have read "A patient presents with a skin and soft tissue defect on the nose..." Our consensus panel discussed this issue and felt that the survey results are still appropriate.

We also would like to recommend to the RUC that the vignette should be modified to specify nose only.

		Pre	Intra	Post	Post-Op	Total	RVU
K-Ref	14302		40			40	3.73
SVY	13153		45			45	2.38
Ref	22116		45			45	2.32

Based on these comparisons, the CP recommends 2.38 work RVUs, the current value for 13153.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: Yes

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☒ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario. 13152 & 13151

FREQUENCY INFORMATION

How was this service previously reported? (if unlisted code, please ensure that the Medicare frequency for this unlisted code is reviewed) 13153

How often do physicians in your specialty perform this service? (ie. commonly, sometimes, rarely)
If the recommendation is from multiple specialties, please provide information for each specialty.

Specialty Dermatology How often? Sometimes

Specialty Otolaryngology How often? Sometimes

Specialty How often?

Estimate the number of times this service might be provided nationally in a one-year period? 3600
If the recommendation is from multiple specialties, please provide the frequency and percentage for each specialty. Please explain the rationale for this estimate. Estimate done 3X more than Medicare population

Specialty Dermatology Frequency 1044 Percentage 29.00 %

Specialty Otolaryngology Frequency 432 Percentage 12.00 %

Specialty Frequency Percentage %

Estimate the number of times this service might be **provided to Medicare patients** nationally in a one-year period? 1200 If this is a recommendation from multiple specialties please estimate frequency and percentage for each specialty. Please explain the rationale for this estimate. Medicare claims data

Specialty Dermatology Frequency 348 Percentage 29.00 %

Specialty Otolaryngology Frequency 144 Percentage 12.00 %

Specialty Frequency Percentage %

Do many physicians perform this service across the United States? Yes

---

Professional Liability Insurance Information (PLI)

If the surveyed code is an existing code and the specialty believes the specialty utilization mix will not change, enter the surveyed existing CPT code number 13153

If this code is a new/revised code or an existing code in which the specialty utilization mix will change, please select another crosswalk based on a similar specialty mix.

AMA/Specialty Society Update Process
Practice Expense Summary of Recommendation
Non Facility Direct Inputs

CPT Long Descriptor:

13100 Repair, complex, trunk; 1.1 cm to 2.5 cm

13101 Repair, complex, trunk; 2.6 cm to 7.5 cm

13102 Repair, complex, trunk; each additional 5 cm

13120 Repair, complex, scalp, arms, and/or legs; 1.1-2.5 cm

13121 Repair, complex, scalp, arms, and/or legs; 2.6 cm to 7.5 cm

13122 Repair, complex, scalp, arms, and/or legs; each additional 5 cm

13131 Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 1.1 cm to 2.5 cm

13132 Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; 2.6 cm to 7.5 cm

13133 Repair, complex, forehead, cheeks, chin, mouth, neck, axillae, genitalia, hands and/or feet; each additional 5cm

13150 Remove Code

13151 Repair, complex, eyelids, nose, ears and/or lips; 1.1-2.5 cm

13152 Repair, complex, eyelids, nose, ears and/or lips; 2.6 cm - 7.5 cm

13153 Repair, complex, eyelids, nose, ears and/or lips; each additional 5 cm

Global Period: **010** Meeting Date: **April 2012**

Please provide a brief description of the process used to develop your recommendation and the composition of your Specialty Society Practice Expense Committee:

The AAD RB/RVS committee has reviewed the RUC approved PE direct inputs for these codes as well as determined from industry data that there are no significant additions or changes to these inputs. The AAD Coding & Reimbursement Task Force as well as the RUC advisors for AAD, ASDS, ACMS and SID serve on the AAD RB/RVS committee.

If you have provided any comparison practice expense inputs on your spreadsheet, please provide a rationale for the selection of codes. Comparison Code Rationale:

Please describe in detail the clinical activities of your staff:

CPT Code: 13100; 13101; 13102; 13120; 13121; 13122; 13131; 13132; 13133; 13150; 13151; 13152; 13153

Specialty Society('s): American Academy of Dermatology

Please see PE Direct input spreadsheet.

AMA/Specialty Society RVS Update Committee Summary of Recommendations
CMS High Expenditure Procedure Codes screen

April 2012

Arthrocentesis-PE Only

This service was identified by CMS in July 2011 through the CMS High Expenditure Procedural Codes screen. Surveys for physician work were reviewed recently for the 2011 Medicare physician payment schedule, but practice expense was not reviewed at that time. In January 2012, the RUC recommended that the practice expense only be reviewed at the April 2012 meeting. The Practice Expense Subcommittee removed three minutes for *provide pre-service education/obtain consent* from each code because they are commonly billed with an Evaluation and Management service. **The RUC reviewed and approved the direct practice expense inputs with minor modifications as recommended by the Practice Expense Subcommittee.**

CPT Code (●New)	Tracking Number	CPT Descriptor	Global Period	Work RVU Recommendation
20600		Arthrocentesis, aspiration and/or injection; small joint or bursa (eg, fingers, toes)	000	0.66 (PE Input Recommendations Only)
20605		intermediate joint or bursa (eg, temporomandibular, acromioclavicular, wrist, elbow or ankle, olecranon bursa)	000	0.68 (PE Input Recommendations Only)
20610		major joint or bursa (eg, shoulder, hip, knee joint, subacromial bursa) (If imaging guidance is performed, see 76942, 77002, 77012, 77021)	000	0.79 (PE Input Recommendations Only)

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

AMA/Specialty Society Update Process
Practice Expense Summary of Recommendation
Facility Direct Inputs

CPT Long Descriptor:
20600, Arthrocentesis, aspiration and/or injection; small joint or bursa (eg, fingers, toes)
20605 Arthrocentesis, aspiration and/or injection; intermediate joint or bursa (eg, temporomandibular, acromioclavicular, wrist, elbow or ankle, olecranon bursa)
20610, Arthrocentesis, aspiration and/or injection; major joint or bursa (eg, shoulder, hip, knee joint, subacromial bursa)

Global Period: 000 Meeting Date: 04/2012

Please provide a brief description of the process used to develop your recommendation and the composition of your Specialty Society Practice Expense Committee:
CPT code 20610 was identified as a CMS high expenditure procedure by the RUC's Relativity Assessment Workgroup and was placed on the list for potential review. The AAOS and ASSH recommended a review of practice expense only since 20610, along with 20600 and 20605 were reviewed for work as part of the 2010 5-Year review. However, none of the 5-year review codes were reviewed for PE at the time. In our comments on the 2012 NPRM we stated to CMS, and later to the RUC RAW workgroup that another review of work would be unnecessary but that review of the 2000 PEAC practice expense inputs would be appropriate and CMS and the RUC agreed. Subsequently, a consensus committee of experts reviewed the current PE details for 20610 and recommended revised facility practice expense inputs and for rank order purposes, also recommends that 20600 and 20605 also be revised for practice expense.

The attached recommendations are for facility practice expense inputs to all three codes in the family.

If you have provided any comparison practice expense inputs on your spreadsheet, please provide a rationale for the selection of codes. Comparison Code Rationale:
Our consensus committee reviewed current PE details and determined that in order to be consistent with current PE subcommittee standards for facility inputs that changes were appropriate. Specifically, we are recommending revised inputs for clinical labor time for all three codes with 6 minutes of total clinical labor time for intra-service discharge related work. This is appropriate because all three procedures are billed more than 50% of the time with an E/M service on the same day of service and therefore the pre and post-service clinical labor time is accounted for in the E/M codes and doesn't need to be included in the procedure's PE.

Please describe in detail the clinical activities of your staff:

Pre-Service Clinical Labor Activities:

none

Intra-Service Clinical Labor Activities:

Same day discharge management

Post-Service Clinical Labor Activities:
None (this removes 10 minutes from previous inputs to be consistent with current PE standards for facility Practice Expense).

AMA/Specialty Society Update Process
Practice Expense Summary of Recommendation
Non Facility Direct Inputs

CPT Long Descriptor:
20600, Arthrocentesis, aspiration and/or injection; small joint or bursa (eg, fingers, toes)
20605 Arthrocentesis, aspiration and/or injection; intermediate joint or bursa (eg, temporomandibular, acromioclavicular, wrist, elbow or ankle, olecranon bursa)
20610, Arthrocentesis, aspiration and/or injection; major joint or bursa (eg, shoulder, hip, knee joint, subacromial bursa)

Global Period: 000 Meeting Date: 04/2012

Please provide a brief description of the process used to develop your recommendation and the composition of your Specialty Society Practice Expense Committee:

CPT code 20610 was identified as a CMS high expenditure procedure by the RUC's Relativity Assessment Workgroup and was placed on the list for potential review. The AAOS and ASSH recommended a review of practice expense only since 20610, along with 20600 and 20605 were reviewed for work as part of the 2010 5-Year review. However, none of the 5-year review codes were reviewed for PE at the time. In our comments on the 2012 NPRM we stated to CMS, and later to the RUC RAW workgroup that another review of work would be unnecessary but that review of the 2000 PEAC practice expense inputs would be appropriate and CMS and the RUC agreed.

Subsequently, a consensus committee of experts reviewed the current PE details for 20610 and recommended revised non-facility practice expense inputs and for rank order purposes, also recommends that 20600 and 20605 also be revised for practice expense.

A reference code must be provided for comparison to the practice expense inputs on your spreadsheet. Please provide a rationale for the selection of reference codes. Comparison Code Rationale:
Our consensus committee reviewed current PE details and determined that in order to be consistent with current PE subcommittee standards for non-facility inputs that changes were appropriate. Specifically, we are recommending revised inputs for clinical labor time for all three codes with 22 total minutes of clinical labor time with zero minutes of pre-service clinical labor time; 19 minutes of total clinical labor time for intra-service related work, and three minutes of post-service clinical labor time for discharge management work. This is appropriate because all three procedures are billed more than 50% of the time with an E/M service on the same day of service and therefore the pre and post-service clinical labor time is accounted for in the E/M codes and doesn't need to be included in the procedure's PE except a minimal amount of post-discharge clinical labor time.

Please describe in detail the clinical activities of your staff:

Pre-Service Clinical Labor Activities:

none

Service Clinical Labor Activities:

We have allocated 19 minutes intra-service clinical labor time for assisting the physician which is consistent with other non-facility PE inputs when a service is performed more than 50% of the time with an E/M service and to have the same intra-service clinical labor time as the physician clinical labor time. Specifically, three minutes for obtaining patient consent and pre-service education (no change from current inputs), two minutes to prepare room, equipment and supplies (no change from current inputs), five minutes assisting physician in procedure (5 minutes less than current inputs to be consistent with the current work intra-service time of 5 minutes), three minutes to monitor patient post-service (no change from current inputs), three minutes to clean the room and equipment (no change from current inputs), and three minutes to check dressing and wounds and provide discharge management instructions (no change from current inputs).

Post-Service Clinical Labor Activities:

We have allocated 3 minutes post-service clinical labor time for follow up phone calls and to call in prescriptions (no change from current inputs). We removed 5 minutes from current inputs for other clinical activity.

AMA/Specialty Society RVS Update Committee Summary of Recommendations
CMS High Expenditure Procedure Codes screen

April 2012

Valve Replacement and CABG Procedures

In July 2011, these services were identified as part of the CMS High Expenditure Procedural Codes screen. In January 2012, the RUC recommended that the specialty societies survey this service for work and practice expense. Rather than conduct a RUC survey the specialty society utilized data from the STS National Adult Cardiac Database, which meets the criteria established by the RUC for the use of extant data. It was also confirmed that the mean is the appropriate data point for analysis of the STS database. While the median is useful for analyzing smaller samples, the STS data has tens of thousands of data points and a mean is therefore more appropriate. The specialty society queried the years 2006-2010 to compare to data obtained from 2000-2004. The RUC reviewed the results of an intensity survey from 76 cardiac surgeons, whom indicated that the intensity of physician work has increased significantly since the codes were last reviewed in 2005 for the 3rd Five-Year Review. The RVU recommendations were calculated by multiplying the intensity measures and the service time, which is the same methodology that was used for valuation for the last review. The RUC did not employ the intensity survey submitted because its use in conjunction with extant data is not clearly permitted outside of the 5 year review under the current RUC policies and procedures.

CPT codes 33405 ***Replacement, aortic valve, with cardiopulmonary bypass; with prosthetic valve other than homograft or stentless valve***
The RUC reviewed the data from 78,332 patients and agreed with the specialty society that the work RVU of 41.32, the current value and below the computed value based on STS database time, appropriately accounts for the physician work required to perform this service. The RUC agreed with the specialty society recommended physician time of 95 minutes pre-service, 197 minutes intra-service and 40 minutes post-service. The RUC agreed that pre-service time equivalent to a pre-service package 4 (difficult patient, difficult procedure), with additional time for evaluation and positioning of the patient, was appropriate for this service. The RUC agreed that an additional 20 minutes of evaluation time was appropriate to review the echocardiogram and angiogram, confirm the set up for the cardiopulmonary bypass and conduct a review of patient and planned procedure with qualified healthcare professionals involved in the service. An additional 12 minutes of positioning is also needed to adequately position the patient and position external equipment on the patient to ensure appropriate nerve protection and comfort. The STS data showed that the intra-service time remained relatively the same (198 to 197 minutes), and the intensity measures have increased. The specialty society indicated and the RUC agreed that the pre-service and post-service, as well as post-operative visits have not changed. The RUC reviewed reference codes with similar time and intensity and noted that CPT code 33031 *Pericardiectomy, subtotal or complete; with cardiopulmonary bypass* (work RVU=45.00) has similar intra-service time at 205 minutes and CPT code 35082 *Direct repair of aneurysm, pseudoaneurysm, or excision (partial or total) and graft insertion, with or without patch graft; for ruptured aneurysm, abdominal aorta* (work RVU=42.09), has similar intra-service time at 180 minutes and similar physician work. The RUC concurred that this service is valued appropriately and should maintain its value. **The RUC recommends a work RVU of 41.32 for CPT code 33405.**

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

CPT code 33430 ***Replacement, mitral valve, with cardiopulmonary bypass***
The RUC reviewed the data set of 15,374 patients and agreed with the specialty society that the work RVU of 50.93, the current value and below the computed value based on STS database time, appropriately accounts for the physician work required to perform this service. The RUC agreed with specialty society recommended physician time of 95 minutes pre-service, 232 minutes intra-service and 40 minutes post-service. The RUC agreed that pre-service time equivalent to a pre-service package 4 (difficult patient, difficult procedure), with additional time for evaluation and positioning of the patient, was appropriate for this service. The RUC agreed that an additional 20 minutes of evaluation time was appropriate to review the echocardiogram and angiogram, confirm the set up for the cardiopulmonary bypass and conduct a review of patient and planned procedure with qualified healthcare professionals involved in the service. An additional 12 minutes of positioning is also needed to adequately position the patient and position external equipment on the patient to ensure appropriate nerve protection and comfort. The STS data showed that the intra-service time has increased from 223 to 232 minutes, and the intensity measures have increased. However, the specialty did not feel that a request for an increase could be justified at this time because the patients have not changed. The specialty society indicated and the RUC agreed that the pre-service and post-service, as well as post-operative visits have not changed. The RUC reviewed comparator codes with similar time and intensity and noted that CPT code 33465 *Replacement, tricuspid valve, with cardiopulmonary bypass* (work RVU=50.72) has similar physician time at 95 minutes pre-service, 211 minutes intra-service and 40 minutes post-service and CPT code 33875 *Descending thoracic aorta graft, with or without bypass* (work RVU=50.72), has similar intra-service time at 240 minutes and similar physician work. The RUC concurred that this service is valued appropriately and should maintain its value. **The RUC recommends a work RVU of 50.93 for CPT code 33430.**

CPT code 33533 ***Coronary artery bypass using arterial graft(s); single arterial graft***
The RUC agreed with the specialty society that there is compelling evidence to increase the value of this code based on an increase in intra-service time, a change in patient population and increased work intensity. Although the overall length of hospital stay was unchanged, there have been increases in the incidence of diabetes, heart failure, cerebrovascular disease and peripheral vascular disease. Most of the composite variables that predict increased morbidity have increased and the use of preoperative ADP blockers has increased. The patient population undergoing surgical myocardial revascularization has changed dramatically due to two factors. First, the drug eluting coronary stent was introduced in 2002-2003 and became prevalent at the very end of the 2000-2004 period used in establishing the current work values. This device has led to dramatic shifts in the surgical population towards patients having severe and diffuse coronary artery disease (and those with diabetes) toward percutaneous intervention. The second major change in the patient population is the prevalence of dual antiplatelet drug therapy that occurred in 2004 when the an FDA panel recommended at least 12 months of such therapy to minimize the occurrence of fatal drug eluting stent thrombosis. Increasing prevalence of dual antiplatelet therapy and the introduction of other agents such as direct thrombin inhibitors and irreversible fractionated heparin products have increased complexity and intensity of obtaining hemostasis during cardiac surgery. This has been compounded by the withdrawal of aprotinin from the marketplace in 2006. This was the only effective hemostatic agent in this anti-platelet drug environment, and was in widespread use during the 2000-2004 index time period.

The RUC reviewed the data set of 29,250 patients and agreed with the specialty recommended physician time of 95 minutes pre-service, 158

CPT five-digit codes, two-digit modifiers, and descriptions only are copyright by the American Medical Association.

minutes intra-service and 40 minutes post-service. The RUC agreed that pre-service time equivalent to a pre-service package 4 (difficult patient, difficult procedure), with additional time for evaluation and positioning of the patient, was appropriate for this service. The RUC agreed that an additional 20 minutes of evaluation time was appropriate to review the echocardiogram and angiogram, confirm the set up for the cardiopulmonary bypass and conduct a review of patient and planned procedure with qualified healthcare professionals involved in the service. An additional 12 minutes of positioning is also needed to adequately position the patient and position external equipment on the patient to ensure appropriate nerve protection and comfort. The STS data showed that the intra-service time has increased from 151 to 158 minutes, and the and the intensity measures have increased The specialty society indicated and the RUC agreed that the pre-service and post-service, as well as post-operative visits have not changed.

The RUC reviewed the results of an intensity survey from 76 cardiac surgeons, but did not employ the intensity survey submitted because its use in conjunction with extant data is not clearly permitted outside of the 5 year review under the current RUC policies and procedures. The RUC noted that this method should be further considered by the Research Subcommittee. The RUC used magnitude estimation and determined that a direct crosswalk to CPT code 33510 *Coronary artery bypass, vein only; single coronary venous graft* (work RVU = 34.98, intra-service time = 154 minutes), is appropriate. The RUC agreed with the specialty society that 33510 is less intense to perform than 33533, since an arterial graft is more complex than a vein graft. However, 33510 has one more post-operative visit than the surveyed code, thus validating the same value for these services. **The RUC recommends a work RVU of 34.98 for CPT code 33533, a direct crosswalk to CPT code 33510.**

Practice Expense

The RUC discussed that the staff type included in practice expense is an RN rather than the more common RN/LPN/MTA blend. The RUC agreed with the specialty society that during past reviews of cardiothoracic services, compelling evidence was accepted to justify the designation of RN as the clinical staff type. The RUC reviewed and approved the direct practice expense inputs as recommended by the Practice Expense Subcommittee.

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
2010 FIVE YEAR REVIEW SUMMARY OF RECOMMENDATION

CPT Code:33405 Tracking Number Specialty Society Recommended RVU: **41.32**
Global Period: 090 RUC Recommended RVU: **41.32**

CPT Descriptor: Replacement, aortic valve, with cardiopulmonary bypass; with prosthetic valve other than homograft or stentless valve

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: The typical patient is a 67 year old male with aortic stenosis and one or more of the following risk factors for mortality or prolonged length of stay:

Diabetes requiring Insulin or oral agents	25%
Peripheral Vascular Disease	8%
Cerebral Vascular Disease	11%
Prior CVA	6%
Cardiogenic Shock	1%

Percentage of Survey Respondents who found Vignette to be Typical: 100%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Kept overnight (less than 24 hours) 0% , Admitted (more than 24 hours) 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Is moderate sedation inherent in your reference code (Office setting)? No
Is moderate sedation inherent in your reference code (Hospital/ASC setting)? No

Description of Pre-Service Work: o Perform Complete or Interval History and Physical Exam.
o Write pre-operative orders for peri-operative medications
o Review pre-operative work-up including relevant x-rays, cardiac catheterization and cardiac echocardiography
o Review any prior history and physical examination (if done)
o Review office notes from referring and primary physicians
o Review laboratory results (CBC, electrolytes, renal and liver function, coagulation)
o Review Cardiology and Pulmonary assessment as indicated
o Review the surgical procedure, post-op recovery in and out of the hospital, expected outcome(s) and any possible complications with patient and family
o Review choice of prosthetic valve (bioprosthetic vs mechanical) as well as anticoagulation implications associated with each valve choice with patient and family
o Obtain informed consent
o Identify patient, mark planned surgical incision site per policy
o Review planned procedure and positioning and draping of patient

o Review trans-esophageal echocardiogram with anesthesiologist and/or cardiologist with special attention to quality of ascending aorta and ventricular function
o Scrub, Gown and Glove
o Prep and drape the skin of the chest, abdomen, and legs from the neck to the ankles including both groin areas
o Perform "Time Out" so confirmation of critical information is ensured, such as the patient's identity, planned procedure, access route, allergies, signed consent, availability of proper equipment, and any unusual circumstances which might influence the procedure

Description of Intra-Service Work: o A standard median sternotomy is made
o Inspect aorta for signs of atherosclerosis and determine cannulation site
o Give systemic heparin and place purse string sutures in aorta and right atrium
o Insert cannulas for cardiopulmonary bypass in the aorta and the right atrium
o Initiate cardiopulmonary bypass
o Place a left ventricular vent via the right superior pulmonary vein
o Place antegrade and retrograde cardioplegia cannulas
o Cross clamp the aorta and administer cardioplegia and topical hypothermia
o Open the ascending aorta
o Remove the native aortic valve
o Debride calcium from aortic annulus taking care to scavenge all debris to avoid particulate emboli
o Measure size of aortic annulus and select prosthesis
o Place sutures in aortic annulus and up through the sewing ring of the prosthetic valve
o Lower prosthesis into place and tie all sutures
o Confirm proper placement and function of prosthesis
o The aortotomy is closed
o Remove clamp with the patient in steep Trendelenberg position to minimize possibility of air or particulate matter embolus to the brain
o Ensure that aortic suture line is hemostatic
o Remove intra-cardiac air identified with intra operative trans esophageal echocardiography
o Place temporary atrial and ventricular pacing wires
o Separate patient from cardiopulmonary bypass
o Evaluate the post-procedure, intra-operative echocardiogram with specific attention to ventricular function, prosthesis function, and perivalvar leak
o When the patient is stable, administer protamine (to reverse heparin)and remove the arterial and venous perfusion cannulas.
o When hemostasis is adequate place mediastinal and, if necessary, pleural drains through separate small incisions
o Close median sternotomy incision

Description of Post-Service Work: Immediate Post-op same day work:
o Apply sterile dressings to the incision
o Remove drapes with close attention to pacing wires (if any), tubes and lines to ensure that none are dislodged or disconnected
o A detailed "hand-off" process is initiated by means of communication with the accepting physicians, nursing staff and other members of the health care team as to the nature of the operation and any complications or events that would require special attention
o Accompany patient to the ICU and direct the team should the patient's condition change en route
o Assure hemodynamic stabilization of the patient which includes review of the patients postoperative chest x-ray and EKG
o Write post operative orders
o Write brief operative note for the patient's chart documenting in the daily progress notes pre- and postoperative diagnoses, operation performed, findings, blood loss, intraoperative IV fluids administered, complications, and specimens sent to pathology (if any)
o Discuss procedure outcome with family and referring physician
Dictate post-op report
o Coordinate care with other physicians

Postoperative Critical Care

- Assess neurological state
- Monitor emergence from anesthesia
- Administer sedatives, paralyzing agents and analgesics as needed
- Evaluate gross neurologic function including level of consciousness, behavioral appropriateness, and presence and nature of focal neurological defect if present
- Repeat evaluation until intraoperative neurologic injury is ruled out.
- Assess hemodynamic condition
- Evaluate cardiac rhythm
- Review 12-lead EKG for signs or ischemia or injury, compare to preoperative tracing
- Assess blood pressure, central venous pressure, pulmonary artery pressures, cardiac output and index
- Administer crystalloid fluids or blood products depending on cardiac index, mixed venous oxygen saturation, hemoglobin, and central filling pressures
- Adjust inotropic and vasoactive agents given by continuous infusion to optimize O2 delivery and minimize adverse end-organ effects
- Carefully evaluate peripheral perfusion by observation and physical exam, correlating findings with invasive monitoring results
- Monitor chest tube bleeding
- Presence of tamponade state is assessed.
- Assess laboratory results, correlate with other findings, and determine the need for blood, blood products including platelets cryoprecipitate and fresh frozen plasma
- Examine breath sounds, observe chest mechanics, assure mid-line tracheal position by physical exam
- Assess ventilator settings, observe underlying respiratory pattern, observe baseline airway pressures generated and minute gas flow
- Confirm endo-tracheal tube placement by review of post-operative chest x-ray
- Monitor lungs for infiltrate/atalectasis
- Assess pleural spaces for fluid collection
- Assess blood gases and adjust ventilator as needed
- Assess for possibility and timing of weaning from ventilator
- Assess adequacy of urine output
- Assess volume status and administer fluids or diuretics as needed
- Monitor distal extremity perfusion
- Discuss interval plans with nursing staff
- Set parameters for interval adjustments in patient treatment
- Chart patient progress notes

Remainder of Post-op hospital work

- Continue to monitor patient's hemodynamic status .
- Inspect all wounds daily for drainage, underlying hematoma, or inflammation
- Assess postoperative pain, use of analgesics, adequacy of response
- Assess character of pulmonary secretions, patients ability to clear airway
- Review vital signs, I&O, laboratory results, patient daily weight
- Review chest radiograph
- Evaluate cardiac monitor for rate, rhythm, presence or absence of arrhythmia
- Assess progress of system recovery, assess risk for development of complications
- Encourage ambulation and vigorous pulmonary physiotherapy
- Carefully assess and monitor postoperative nutritional status as maintained by both enteral (if necessary) and oral feedings
- Remove chest tube when appropriate (usually 24-48 hours post-operatively)
- Answer patient/family questions
- Write orders for post-op labs, films, medications, diet, and patient activity
- If indicated, implement systemic anticoagulation at earlier possible opportunity with heparin and subsequent warfarin therapy
- Discuss patient progress with referring physician (verbal and written)
- Coordinate care with other physicians
- Document evaluation, patient progress and plan in medical record
- At discharge, carefully explain to patient and a family member dietary management, activities permitted, bathing, return appointment to office, etc.
- Coordinate care with other physicians

- Answer patient/family questions
- Write prescriptions and discharge instructions
- Explain nature, purpose and expected duration of use of new medications. Detailed instructions on warfarin therapy and drug as well as food interactions. If needed, arrange and explain the need for frequent lab testing until the warfarin dose is stabilized. Specific instructions on the need to notify other treating physicians or dentists of the presence of a heart valve abnormality and the need for prophylactic peri-procedural antibiotics. Review patients home medications
- Dictate discharge summary
- Communicate with patient's primary care physician(s)

Post-Service intensity/complexity		

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

In response to a request by CMS to the RUC, the STS National Adult Cardiac Database was queried for the years 2006-2010 to compare to data obtained from 2000-2004 to support the current valuation. The data set included 78,332 patients and met the criteria established for database utilization by the RUC. An analysis of annual procedural

performance as captured in the database, compared to Medicare Utilization files indicates that more than 95% of performed cardiac procedures are now included.

Data extraction and reporting are identical to that performed during the 2005 5-year review. Briefly, only those records that could be unequivocally and exclusively matched to this CPT code were utilized. Patients were excluded if other cardiac procedures were performed simultaneously, if the patient had prior CABG or prior Valve replacement, or if they returned to the operative room for another procedure during the index hospitalization. Length of hospital stay was truncated to 90 days if greater than 90 days.

Additional pre-service time has been recommended for evaluation and positioning of patient. For pre-service evaluation 10 minutes have been added for review echocardiogram and angiogram, as well as real time review of transesophageal echo performed prior to prep to confirm diagnosis, annular size and availability of appropriate sized valve prosthesis. 3 minutes has been added to confirm set up for cardiopulmonary bypass, availability of blood, availability of perfusionists. 7 minutes has been added to perform briefing and time out (2 separable events) with anesthesiology, nursing, perfusion, physician assistant anesthesia technician and other support staff with complete review of patient and planned procedure. For pre-service positioning of patient, 12 minutes has been added to place external defibrillator pads in correct position to effect defibrillation and not interfere with planned or potential incisions. Place roll midline upper thoracic to enable sternal separation, or beanbag position for thoractomy approach with right chest rotated 45 degrees to hip plane. Ensure patient has bilateral ulna nerve protection and carefully secure patient arms at his side. Confirm appropriate fixed, ophthalmologic protection prior to deployment of sterile drapes and any retraction aid devices. Position and confirm reliable signals from additional EKG electrodes to syncrhonize intra-aortic balloon pump (all cases, preparation for potential need to separate from cardiopulmonary bypass). Postion legs in frogleg after circumferential prep, ensure protection of lateral fibular condyle to prevent peroneal nerve injury.

An intensity survey was performed to evaluate this element of physician work, and the reference service list is submitted as an exhibit. The survey was sent to a random sample of cardiac surgeons, with 76 respondents. Respondents also answered the 5-year review questions. The survey indicated that physician work has increased significantly since its last valuation, and that the intraservice work has increased from 0.105 to 0.112 per unit time.

The STS data showed that the intraservice time has decreased from 198 to 197 minutes. The overall length of hospital stay was unchanged as was the ventilator time. The patients were 1.7 years older, and more had diabetes. Overall, the prevalence of comorbid features, complications and overall demographics are presented in comparison to the data from 2000-2004 in a handout. The building block method employed in the 2005 5-year review was utilized with new inputs for intraservice time, intraservice work per unit time and unchanged time and visit inputs. This resulted in a work value of **42.58** which is an increase compared to the current value of 41.32. The building block is included as a separate document.

The expert panel reviewed the data, and recommends that the current value of **41.32** be retained along with the current time and visit inputs. It is likely that the patient population will change significantly in the near future with the introduction of effective transcatheter alternatives to surgical aortic valve replacement, and may warrant reintroduction into the rolling review process.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

- ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
- ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
- ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
- ☐ Multiple codes are used to maintain consistency with similar codes.
- ☐ Historical precedents.
- ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

Professional Liability Insurance Information (PLI)

Does the reference CPT code selected for physician work serve as a reasonable reference for PLI crosswalk? (ie. similar work RVU, and specialty) Yes

If no, please select another crosswalk and provide a brief rationale. 33405

Indicate what risk factor the new/revised code should be assigned to determine PLI relative value. Surgical

Compelling Evidence

The RUC operates with the initial presumption that the current values assigned to the codes under review are correct. The argument for a change must be substantial and meet the RUC's compelling evidence standards listed in the Instructions Document. Please list your compelling evidence below (if appropriate).

N/A

Five-Year Review Specific Questions

Please indicate the number of survey respondent percentages responding to each of the following questions (for example 0.05 = 5%).

Has the work of performing this service changed in the past 5 years? Yes 78% No 22%

A. This service represents new technology? Yes 53% No 26%

Of survey respondents, who said yes, the new technology affected the work:

Less Work: 3% Same Work: 4% More Work: 54%

B. This service reflects new technology that has become more familiar: Yes 37% No 37%

C. Patients requiring this service are now:

More complex (more work) 71% Less complex (less work) 0% No change in complexity 8%

D. The typical site-of-service has changed:

From outpatient to inpatient 5% From inpatient to outpatient 0% No change 72%

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
2010 FIVE YEAR REVIEW SUMMARY OF RECOMMENDATION

CPT Code:33430 Tracking Number Specialty Society Recommended RVU: **50.93**
Global Period: 090 RUC Recommended RVU: **50.93**

CPT Descriptor: Replacement, mitral valve, with cardiopulmonary bypass

---

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: The typical patient is a 61 year old female with mitral valve disease and one or more of the following risk factors for mortality or prolonged length of stay:

Diabetes requiring Insulin or oral agents	19%
Peripheral Vascular Disease	6%
Cerebral Vascular Disease	15%
Prior CVA	11%
Cardiogenic Shock	3%

Percentage of Survey Respondents who found Vignette to be Typical: 100%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Kept overnight (less than 24 hours) 0% , Admitted (more than 24 hours) 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Is moderate sedation inherent in your reference code (Office setting)? No
Is moderate sedation inherent in your reference code (Hospital/ASC setting)? No

---

Description of Pre-Service Work: o Perform Complete or Interval History and Physical Exam.
o Write pre-operative orders for peri-operative medications
o Review pre-operative work-up including relevant x-rays, cardiac catheterization and cardiac echocardiography
o Review any prior history and physical examination (if done)
o Review office notes from referring and primary physicians
o Review laboratory results (CBC, electrolytes, renal and liver function, coagulation)
o Review Cardiology and pulmonary assessment as indicated
o Review the surgical procedure, post-op recovery in and out of the hospital, expected outcome(s) and any possible complications with patient and family
o Review choice of prosthetic valve (bioprosthetic vs mechanical) as well as anticoagulation implications associated with each valve choice with patient and family
o Obtain informed consent
o Identify patient, mark planned surgical incision site per policy
o Review planned procedure and positioning and draping of patient
o Review trans-esophageal echocardiogram with anesthesiologist and/or cardiologist with special attention to quality of ascending aorta and ventricular function

o Scrub, Gown and Glove
o Prep and drape the skin of the chest, abdomen, and legs from the neck to the ankles including both groin areas
o Perform "Time Out" so confirmation of critical information is ensured, such as the patient's identity, planned procedure, access route, allergies, signed consent, availability of proper equipment, and any unusual circumstances which might influence the procedure

Description of Intra-Service Work: o A standard median sternotomy is made
o Inspect aorta for signs of atherosclerosis and determine cannulation site
o Give systemic heparin and place purse string sutures in aorta and right atrium
o Insert cannulas for cardiopulmonary bypass in the aorta and the Superior and Inferior Vena Cavae for bicaval venous drainage
o Initiate cardiopulmonary bypass
o Check with anesthesiologist and/or perfusionist regarding activated clotting time to assess level of heparinization
o Dissect the inter-atrial plane
o Initiate systemic cooling
o Cross clamp the aorta and administer cardioplegia and topical hypothermia
o Open the left atrium
o Remove any intra-atrial thrombus
o Oversew the left atrial appendage
o Inspect and analyze pathology of the mitral valve
o Perform partial valve resection preserving posterior leaflet and as much of the anterior leaflet as possible
o Use sizer to determine appropriate sized prosthesis
o Place pledgeted mattress sutures in the mitral annulus and up through the sewing ring of valve
o Seat valve, verify no suture entrapment on valve struts, tie and cut all sutures
o Verify free motion of valve leaflets, especially with mechanical prostheses
o Close left atrium with two layers of suture
o Place patient in steep Trendelenberg position and remove aortic cross clamp taking care to avoid cerebral air embolus
o Remove intra-cardiac air monitoring with echocardiography
o Place temporary pacing wires and begin atrial, atrio-ventricular, or ventricular pacing if indicated
o Discontinue cardiopulmonary bypass, monitoring hemodynamics with arterial and pulmonary artery lines
o Evaluate the post-procedure, intra-operative echocardiogram specifically examining for ventricular function, prosthesis function, and perivalvar leak
o When the patient is stable, give protamine and remove the arterial and venous cannulas.
o When hemostasis is adequate place pericardial and, if necessary, pleural drains
o Close the median sternotomy wound.

Description of Post-Service Work: Immediate Post-op same day work:
o Apply sterile dressings to the incision
o Remove drapes with close attention to pacing wires (if any), tubes and lines to ensure that none are dislodged or disconnected
o A detailed "hand-off" process is initiated by means of communication with the accepting physicians, nursing staff and other members of the health care team as to the nature of the operation and any complications or events that would require special attention
o Accompany patient to the ICU and direct the team should the patient's condition change en route
o Assure hemodynamic stabilization of the patient which includes review of the patients postoperative chest x-ray and EKG
o Write post operative orders
o Write brief operative note for the patient's chart documenting in the daily progress notes pre- and postoperative diagnoses, operation performed, findings, blood loss, intraoperative IV fluids administered, complications, and specimens sent to pathology (if any)
o Discuss procedure outcome with family and referring physician
Dictate post-op report
o Coordinate care with other physicians

Postoperative Critical Care

- Assess neurological state
- Monitor emergence from anesthesia
- Administer sedatives, paralyzing agents and analgesics as needed
- Evaluate gross neurologic function including level of consciousness, behavioral appropriateness, and presence and nature of focal neurological defect if present
- Repeat evaluation until intraoperative neurologic injury is ruled out.
- Assess hemodynamic condition
- Evaluate cardiac rhythm
- Review 12-lead EKG for signs or ischemia or injury, compare to preoperative tracing
- Assess blood pressure, central venous pressure, pulmonary artery pressures, cardiac output and index
- Administer crystalloid fluids or blood products depending on cardiac index, mixed venous oxygen saturation, hemoglobin, and central filling pressures
- Adjust inotropic and vasoactive agents given by continuous infusion to optimize O2 delivery and minimize adverse end-organ effects
- Carefully evaluate peripheral perfusion by observation and physical exam, correlating findings with invasive monitoring results
- Monitor chest tube bleeding
- Presence of tamponade state is assessed.
- Assess laboratory results, correlate with other findings, and determine the need for blood, blood products including platelets cryoprecipitate and fresh frozen plasma
- Examine breath sounds, observe chest mechanics, assure mid-line tracheal position by physical exam
- Assess ventilator settings, observe underlying respiratory pattern, observe baseline airway pressures generated and minute gas flow
- Confirm endo-tracheal tube placement by review of post-operative chest x-ray
- Monitor lungs for infiltrate/atalectasis
- Assess pleural spaces for fluid collection
- Assess blood gases and adjust ventilator as needed
- Assess for possibility and timing of weaning from ventilator
- Assess adequacy of urine output
- Monitor distal extremity perfusion
- Discuss interval plans with nursing staff
- Set parameters for interval adjustments in patient treatment
- Chart patient progress notes

Remainder of Post-op hospital work

- Continue to monitor patient's hemodynamic status .
- Inspect all wounds daily for drainage, underlying hematoma, or inflammation
- Assess postoperative pain, use of analgesics, adequacy of response
- Assess character of pulmonary secretions, patients ability to clear airway
- Review vital signs, I&O, laboratory results, patient daily weight
- Review chest radiograph
- Evaluate cardiac monitor for rate, rhythm, presence or absence of arrhythmia
- Encourage ambulation and vigorous pulmonary physiotherapy
- Carefully assess and monitor postoperative nutritional status as maintained by both enteral (if necessary) and oral feedings
- Remove chest tube when appropriate (usually 24-48 hours post-operatively)
- Answer patient/family questions
- Write orders for post-op labs, films, medications, diet, and patient activity
- If indicated, implement systemic anticoagulation at earlier possible opportunity with heparin and subsequent warfarin therapy
- Discuss patient progress with referring physician (verbal and written)
- Coordinate care with other physicians
- Document evaluation, patient progress and plan in medical record
- At discharge, carefully explain to patient and a family member dietary management, activities permitted, bathing, return appointment to office, etc.
- Coordinate care with other physicians
- Write prescriptions and discharge instructions

- Explain nature, purpose and expected duration of use of new medications. Detailed instructions on warfarin therapy and drug as well as food interactions. If needed, arrange and explain the need for frequent lab testing until the warfarin dose is stabilized. Specific instructions on the need to notify other treating physicians or dentists of the presence of a heart valve abnormality and the need for prophylactic peri-procedural antibiotics. Review patients home medications
- Dictate discharge summary
- Communicate with patient's primary care physician(s)

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

In response to a request by CMS to the RUC, the STS National Adult Cardiac Database was queried for the years 2006-2010 to compare to data obtained from 2000-2004 to support the current valuation. The data set included 15,374 patients and met the criteria established for database utilization by the RUC. An analysis of annual procedural

performance as captured in the database, compared to Medicare Utilization files indicates that more than 95% of performed cardiac procedures are now included.

Data extraction and reporting are identical to that performed during the 2005 5-year review. Briefly, only those records that could be unequivocally and exclusively matched to this CPT code were utilized. Patients were excluded if other cardiac procedures were performed simultaneously, if the patient had prior CABG or prior Valve replacement, or if they returned to the operative room for another procedure during the index hospitalization. Length of hospital stay was truncated to 90 days if greater than 90 days.

Additional pre-service time has been recommended for evaluation and positioning of patient. For pre-service evaluation 10 minutes have been added for review echocardiogram and angiogram, as well as real time review of transesophageal echo performed prior to prep to confirm diagnosis, annular size and availability of appropriate sized valve prosthesis. 3 minutes has been added to confirm set up for cardiopulmonary bypass, availability of blood, availability of perfusionists. 7 minutes has been added to perform briefing and time out (2 separable events) with anesthesiology, nursing, perfusion, physician assistant anesthesia technician and other support staff with complete review of patient and planned procedure. For pre-service positioning of patient, 12 minutes has been added to place external defibrillator pads in correct position to effect defibrillation and not interfere with planned or potential incisions. Place roll midline upper thoracic to enable sternal separation, or beanbag position for thoractomy approach with right chest rotated 45 degrees to hip plane. Ensure patient has bilateral ulna nerve protection and carefully secure patient arms at his side. Confirm appropriate fixed, ophthalmologic protection prior to deployment of sterile drapes and any retraction aid devices. Position and confirm reliable signals from additional EKG electrodes to syncrhonize intra-aortic balloon pump (all cases, preparation for potential need to separate from cardiopulmonary bypass). Postion legs in frogleg after circumferential prep, ensure protection of lateral fibular condyle to prevent peroneal nerve injury.

An intensity survey was performed to evaluate this element of physician work, and the reference service list is submitted as an exhibit. The survey was sent to a random sample of cardiac surgeons, with 76 respondents. Respondents also answered the 5-year review questions. The survey indicated that physician work has increased significantly since its last valuation, and that the intraservice work has increased from 0.109 to 0.112 per unit time.

The STS data showed that the intraservice time has increased from 223 to 232 minutes. The overall length of hospital stay was unchanged as was the ventilator time. The patients were 0.2 years younger, and more had diabetes and cerebrovascular disease. Overall, the prevalence of comorbid features, complications and overall demographics are presented in comparison to the data from 2000-2004 in a handout. The building block method employed in the 2005 5-year review was utilized with new inputs for intraservice time, intraservice work per unit time and unchanged time and visit inputs. This resulted in a work value of **52.59** which is an increase compared to the current value of 50.93. The building block is included as a separate document.

The expert panel reviewed the data, and recommends that the current value of **50.93** be retained along with the current time and visit inputs. It is not likely that the patient population will change significantly in the near future as transcatheter treatments have not been effective.

SERVICES REPORTED WITH MULTIPLE CPT CODES

AMA/SPECIALTY SOCIETY RVS UPDATE PROCESS
2010 FIVE YEAR REVIEW SUMMARY OF RECOMMENDATION

CPT Code:33533 Tracking Number Specialty Society Recommended RVU: **35.39**
Global Period: 090 RUC Recommended RVU: **34.98**

CPT Descriptor: Coronary artery bypass, using arterial graft(s); single arterial graft

---

CLINICAL DESCRIPTION OF SERVICE:

Vignette Used in Survey: The typical patient is a 62 year old male with significant coronary artery disease and one or more of the following risk factors for mortality or prolonged length of stay:

Diabetes requiring Insulin or oral agents	33%
Peripheral Vascular Disease	13%
Cerebral Vascular Disease	12%
Prior CVA	6%
Cardiogenic Shock	1%

Percentage of Survey Respondents who found Vignette to be Typical: 100%

Site of Service (Complete for 010 and 090 Globals Only)

Percent of survey respondents who stated they perform the procedure; In the hospital 0% , In the ASC 0%, In the office 0%

Percent of survey respondents who stated they typically perform this procedure in the hospital, stated the patient is; Discharged the same day 0% , Kept overnight (less than 24 hours) 0% , Admitted (more than 24 hours) 0%

Percent of survey respondents who stated that if the patient is typically kept overnight also stated that they perform an E&M service later on the same day 0%

Moderate Sedation

Is moderate sedation inherent to this procedure in the Hospital/ASC setting? No
Percent of survey respondents who stated moderate sedation is typical in the Hospital/ASC setting? 0%

Is moderate sedation inherent to this procedure in the office setting? No
Percent of survey respondents who stated moderate sedation is typical in the office setting? 0%

Is moderate sedation inherent in your reference code (Office setting)? No
Is moderate sedation inherent in your reference code (Hospital/ASC setting)? No

---

Description of Pre-Service Work: o Perform Complete or Interval History and Physical Exam.
o Write pre-operative orders for peri-operative medications
o Review pre-operative work-up including relevant x-rays, cardiac catheterization and cardiac echocardiography
o Review any prior history and physical examination (if done)
o Review office notes from referring and primary physicians
o Review laboratory results (CBC, electrolytes, renal and liver function, coagulation)
o Review Cardiology and pulmonary assessment as indicated
o Review the surgical procedure, post-op recovery in and out of the hospital, expected outcome(s) and any possible complications with patient and family
o Obtain informed consent
o Identify patient, mark planned surgical incision site per policy
o Review planned procedure and positioning and draping of patient
o Review trans-esophageal echocardiogram with anesthesiologist and/or cardiologist with special attention to quality of ascending aorta and ventricular function
o Scrub, Gown and Glove

o Prep and drape the skin of the chest, abdomen, and legs from the neck to the ankles including both groin areas
o Prep and drape arm if radial artery graft planned
o Perform "Time Out" so confirmation of critical information is ensured, such as the patient's identity, planned procedure, access route, allergies, signed consent, availability of proper equipment, and any unusual circumstances which might influence the procedure

Description of Intra-Service Work: o A standard median sternotomy incision is made
o Dissect Left Internal Mammary Artery using electrocautery and apply clips to vessel branches on LIMA
o Administer systemic heparin
o Assess chest wall for bleeding and cauterize as necessary
o Incise pericardium
o Inspect aorta for signs of atherosclerosis and determine cannulation site
o Determine appropriate cannulas to use based on anatomy and patient BSA
o Place purse string sutures in aorta and right atrium
o Check with anesthesiologist and/or perfusionist regarding activated clotting time value to assess level of heparinization
o Insert cannulas for cardiopulmonary bypass in the aorta and the right atrium
o Initiate cardiopulmonary bypass
o Place antegrade and retrograde (if necessary) cardioplegia cannulas if cardiac arrest planned
o Cross clamp the aorta and administer cardioplegia and topical hypothermia
o Perform coronary arteriotomy
o Perform end-to-side LIMA anastomosis to target coronary vessel using fine monofilament suture and optical magnification
o Remove cross-clamp taking care to avoid cerebral air embolus
o Place temporary pacing wires and begin atrial, atrio-ventricular, or ventricular pacing if indicated
o Discontinue cardiopulmonary bypass
o Evaluate the post-procedure, intra-operative echocardiogram specifically examining for ventricular function and regional wall motion abnormalities
o When the patient is stable, administer protamine (to reverse heparin) and remove the arterial and venous cannulas.

o When hemostasis is adequate place pericardial and, if necessary, pleural drains through separate small incisions
o The median sternotomy is closed

Description of Post-Service Work: Immediate Post-op same day work:
o Apply sterile dressings to the incision
o Remove drapes with close attention to pacing wires (if any), tubes and lines to ensure that none are dislodged or disconnected
o A detailed "hand-off" process is initiated by means of communication with the accepting physicians, nursing staff and other members of the health care team as to the nature of the operation and any complications or events that would require special attention
o Accompany patient to the ICU and direct the team should the patient's condition change en route
o Assure hemodynamic stabilization of the patient which includes review of the patients postoperative chest x-ray and EKG
o Write post operative orders
o Write brief operative note for the patient's chart documenting in the daily progress notes pre- and postoperative diagnoses, operation performed, findings, blood loss, intraoperative IV fluids administered, complications, and specimens sent to pathology (if any)
o Discuss procedure outcome with family and referring physician
Dictate post-op report
o Coordinate care with other physicians

Postoperative Critical Care

o Assess neurological state
o Monitor emergence from anesthesia
o Administer sedatives, paralyzing agents and analgesics as needed

- Evaluate gross neurologic function including level of consciousness, behavioral appropriateness, and presence and nature of focal neurological defect if present
- Repeat evaluation until intraoperative neurologic injury is ruled out.
- Assess hemodynamic condition
- Evaluate cardiac rhythm
- Review 12-lead EKG for signs or ischemia or injury, compare to preoperative tracing
- Assess blood pressure, central venous pressure, pulmonary artery pressures, cardiac output and index
- Administer crystalloid fluids or blood products depending on cardiac index, mixed venous oxygen saturation, hemoglobin, and central filling pressures
- Adjust inotropic and vasoactive agents given by continuous infusion to optimize O2 delivery and minimize adverse end-organ effects
- Carefully evaluate peripheral perfusion by observation and physical exam, correlating findings with invasive monitoring results
- Monitor chest tube bleeding
- Presence of tamponade state is assessed.
- Assess laboratory results, correlate with other findings, and determine the need for blood, blood products including platelets cryoprecipitate and fresh frozen plasma
- Examine breath sounds, observe chest mechanics, assure mid-line tracheal position by physical exam
- Assess ventilator settings, observe underlying respiratory pattern, observe baseline airway pressures generated and minute gas flow
- Confirm endo-tracheal tube placement by review of post-operative chest x-ray
- Monitor lungs for infiltrate/atalectasis
- Assess pleural spaces for fluid collection
- Assess blood gases and adjust ventilator as needed
- Assess for possibility and timing of weaning from ventilator
- Assess adequacy of urine output
- Monitor distal extremity perfusion
- Discuss interval plans with nursing staff
- Set parameters for interval adjustments in patient treatment
- Chart patient progress notes

Remainder of Post-op hospital work

- Continue to monitor patient's hemodynamic status .
- Inspect all wounds daily for drainage, underlying hematoma, or inflammation
- Assess postoperative pain, use of analgesics, adequacy of response
- Assess character of pulmonary secretions, patients ability to clear airway
- Review vital signs, I&O, laboratory results, patient daily weight
- Review chest radiograph
- Evaluate cardiac monitor for rate, rhythm, presence or absence of arrhythmia
- Encourage ambulation and vigorous pulmonary physiotherapy
- Carefully assess and monitor postoperative nutritional status as maintained by both enteral (if necessary) and oral feedings
- Remove chest tube when appropriate (usually 24-48 hours post-operatively)
- Answer patient/family questions
- Write orders for post-op labs, films, medications, diet, and patient activity
- Discuss patient progress with referring physician (verbal and written)
- Coordinate care with other physicians
- Document evaluation, patient progress and plan in medical record
- At discharge, carefully explain to patient and a family member dietary management, activities permitted, bathing, return appointment to office, etc.
- Coordinate care with other physicians
- Write prescriptions and discharge instructions
- Explain nature, purpose and expected duration of use of new medications. Detailed instructions on warfarin therapy and drug as well as food interactions. If needed, arrange and explain the need for frequent lab testing until the warfarin dose is stabilized. Specific instructions on the need to notify other treating physicians or dentists of the presence of a heart valve abnormality and the need for prophylactic peri-procedural antibiotics. Review patients home medications
- Dictate discharge summary
- Communicate with patient's primary care physician(s

SURVEY DATA

INTENSITY/COMPLEXITY MEASURES (Mean)		(of those that selected Key Reference code)
Mental Effort and Judgment (Mean)		
The number of possible diagnosis and/or the number of management options that must be considered		
The amount and/or complexity of medical records, diagnostic tests, and/or other information that must be reviewed and analyzed		
Urgency of medical decision making		
Technical Skill/Physical Effort (Mean)		
Technical skill required		
Physical effort required		
Psychological Stress (Mean)		
The risk of significant complications, morbidity and/or mortality		
Outcome depends on the skill and judgment of physician		
Estimated risk of malpractice suit with poor outcome		

INTENSITY/COMPLEXITY MEASURES	CPT Code	Reference Service 1
Time Segments (Mean)		
Pre-Service intensity/complexity		
Intra-Service intensity/complexity		
Post-Service intensity/complexity		

Additional Rationale and Comments

Describe the process by which your specialty society reached your final recommendation. *If your society has used an IWPUT analysis, please refer to the Instructions for Specialty Societies Developing Work Relative Value Recommendations for the appropriate formula and format.*

In response to a request by CMS to the RUC, the STS National Adult Cardiac Database was queried for the years 2006-2010 to compare to data obtained from 2000-2004 to support the current valuation. The data set included 29,250 patients and met the criteria established for database utilization by the RUC. An analysis of annual procedural

performance as captured in the database, compared to Medicare Utilization files indicates that more than 95% of performed cardiac procedures are now included.

Data extraction and reporting are identical to that performed during the 2005 5-year review. Briefly, only those records that could be unequivocally and exclusively matched to this CPT code were utilized. Patients were excluded if other cardiac procedures were performed simultaneously, if the patient had prior CABG or prior Valve replacement, or if they returned to the operative room for another procedure during the index hospitalization. Length of hospital stay was truncated to 90 days if greater than 90 days.

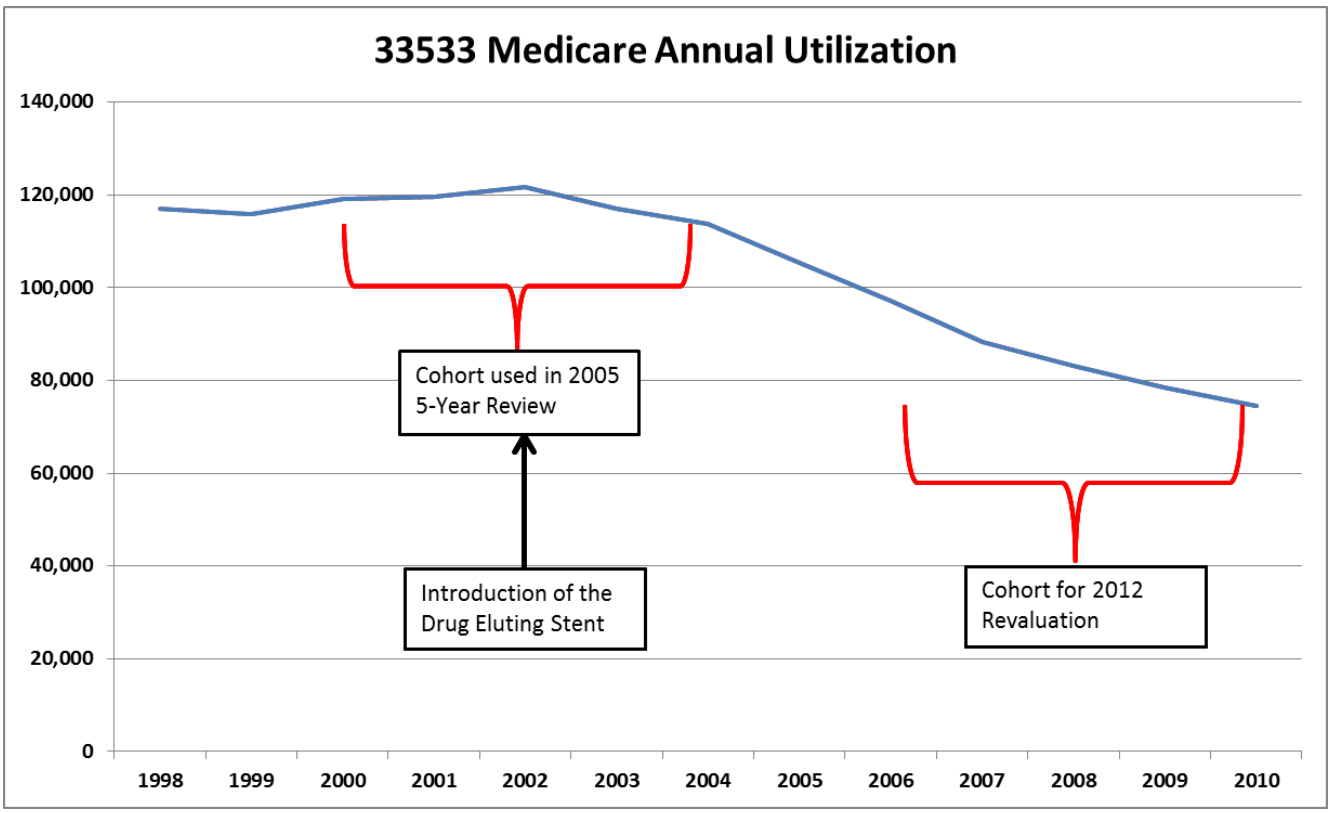
Additional pre-service time has been recommended for evaluation and positioning of patient. For pre-service evaluation 10 minutes have been added for review echocardiogram and angiogram, as well as real time review of transesophageal echo performed prior to prep to confirm diagnosis, rule out inter-atrial communication and valvular heart disease, and to ensure that no new wall motion abnormalites or reduction in ventriclar function has occured since preoperative studies were obtained. 3 minutes has been added to confirm set up for cardiopulmonary bypass, availability of blood, availability of perfusionists. 7 minutes has been added to perform briefing and time out (2 separable events) with anesthesiology, nursing, perfusion, physician assistant anesthesia technician and other support staff with complete review of patient and planned procedure. For pre-service positioning of patient, 12 minutes has been added to place external defibrillator pads in correct position to effect defibrillation and not interfere with planned or potential incisions. Place roll midline upper thoracic to enable sternal separation, or beanbag position for thoractomy approach with right chest rotated 45 degrees to hip plane. Ensure patient has bilateral ulna nerve protection and carefully secure patient arms at his side. Confirm appropriate fixed, ophthalmologic protection prior to deployment of sterile drapes and any retraction aid devices. Position and confirm reliable signals from additional EKG electrodes to syncrhonize intra-aortic balloon pump (all cases, preparation for potential need to separate from cardiopulmonary bypass). Postion legs in frogleg after circumferential prep, ensure protection of lateral fibular condyle to prevent peroneal nerve injury.

An intensity survey was performed to evaluate this element of physician work, and the reference service list is submitted as an exhibit. The survey was sent to a random sample of cardiac surgeons, with 76 respondents. Respondents also answered the 5-year review questions. The survey indicated that physician work has increased significantly since its last valuation, and that the intraservice work has increased from 0.100 to 0.106 per unit time.

The STS data showed that the intraservice time has increased from 151 to 158 minutes, and there were increases in many of the indicators of critical illness. The overall length of hospital stay was unchanged. The prevalence of comorbid features, complications and overall demographics are presented in comparison to the data from 2000-2004 in a handout. The average patient age has decreased by 0.4 years. There have been increases in the incidence of diabetes, heart failure, cerebrovascular disease and peripheral vascular disease. Most of the composite variables that predict increased morbidity have increased. The use of preoperative ADP blockers, which include clopidogrel and prasugrel has increased from 13% to 17%. This was associated with a definitional change from at any time prior to surgery to within 5 days of surgery, a further indicator of increased antiplatelet agent activity at the time of surgery. An expert panel reviewed the data and recommended no change in the number or level of postoperative visits from those already determined in 2005 based upon these data elements.

The building block method employed in the 2005 5-year review was utilized with new inputs for intraservice time, intraservice work per unit time and unchanged time and visit inputs. This resulted in a work value of **35.39** which is an increase compared to the current value of 33.75. The building block is included as a separate document.

We believe that compelling evidence is present to justify this recommended new work value.



The first element of compelling evidence is the indisputable increase in measured intraservice time.

The second element of compelling evidence is the change in patient population to one with more comorbidity and more surgical risk.

The third element of compelling evidence is the survey respondent's assessment of the patient population and work intensity.

The patient population undergoing surgical myocardial revascularization has changed dramatically due to two factors.

First, the drug eluting coronary stent was introduced in 2002-3 and became prevalent at the very end of the 2000-2004 period used in establishing the current work values. This device has led to dramatic shifts in the patient population toward percutaneous intervention as in the following graph:

This shift of patients from surgery to percutaneous intervention has not been uniform, but has rather enriched the surgical population with patients having severe and diffuse coronary artery disease (and those with diabetes). There have been multiple publications from randomized clinical trials and registries that indicate that PCI is being performed in patients who previously would have had surgery, but whose coronary anatomy is less complex and diffuse and thus more amenable to stenting. These factors have been recently embodied in revisions to the CABG/PCI guidelines and the ACCF/AHA Appropriateness Criteria for Revascularization. To a significant extent, these recommendations have been responsive to cardiology practice rather than directive. The impact of these changing patterns has been to increase the severity of distal coronary disease and to present the surgeon with smaller diameter and more diseased coronary "targets" for anastomosis.

The second major change in the patient population is the prevalence of dual antiplatelet drug therapy that occurred in 2004 when the an FDA panel recommended at least 12 months of such therapy to minimize the occurrence of fatal drug eluting stent thrombosis. This has become essentially indefinite therapy in patient who can tolerate it. In addition, patients are being "loaded" with these agents prior to diagnostic cardiac catheterization in anticipation of percutaneous intervention, only to be found to require referral for coronary bypass grafting. The increasing prevalence of dual antiplatelet therapy and the introduction of other agents such as direct thrombin inhibitors and irreversible fractionated heparin products have increased complexity and intensity of obtaining hemostasis during cardiac surgery.

This has been compounded by the withdrawal of aprotinin from the marketplace in 2006. This was the only effective hemostatic agent in this anti-platelet drug environment, and was in widespread use during the 2000-2004 index time period.

References are included with this application in support.

SERVICES REPORTED WITH MULTIPLE CPT CODES

1. Is this code typically reported on the same date with other CPT codes? If yes, please respond to the following questions: No

   Why is the procedure reported using multiple codes instead of just one code? (Check all that apply.)

   - ☐ The surveyed code is an add-on code or a base code expected to be reported with an add-on code.
   - ☐ Different specialties work together to accomplish the procedure; each specialty codes its part of the physician work using different codes.
   - ☐ Multiple codes allow flexibility to describe exactly what components the procedure included.
   - ☐ Multiple codes are used to maintain consistency with similar codes.
   - ☐ Historical precedents.
   - ☐ Other reason (please explain)

2. Please provide a table listing the typical scenario where this code is reported with multiple codes. Include the CPT codes, global period, work RVUs, pre, intra, and post-time for each, summing all of these data and accounting for relevant multiple procedure reduction policies. If more than one physician is involved in the provision of the total service, please indicate which physician is performing and reporting each CPT code in your scenario.

Professional Liability Insurance Information (PLI)

Does the reference CPT code selected for physician work serve as a reasonable reference for PLI crosswalk? (ie. similar work RVU, and specialty) Yes

If no, please select another crosswalk and provide a brief rationale. 33533

Indicate what risk factor the new/revised code should be assigned to determine PLI relative value. Surgical

---

Compelling Evidence

The RUC operates with the initial presumption that the current values assigned to the codes under review are correct. The argument for a change must be substantial and meet the RUC's compelling evidence standards listed in the Instructions Document. Please list your compelling evidence below (if appropriate).
See rationale above

Five-Year Review Specific Questions

Please indicate the number of survey respondent percentages responding to each of the following questions (for example 0.05 = 5%).

Has the work of performing this service changed in the past 5 years? Yes 70% No 30%

A. This service represents new technology? Yes 33% No 43%

Of survey respondents, who said yes, the new technology affected the work:

Less Work: 0% Same Work: 70% More Work: 39%

B. This service reflects new technology that has become more familiar: Yes 30% No 33%

C. Patients requiring this service are now:

More complex (more work) 59% Less complex (less work) 0% No change in complexity 11%

D. The typical site-of-service has changed:

From outpatient to inpatient 7% From inpatient to outpatient 0% No change 66%

Specialty Society('s): STS

AMA/Specialty Society Update Process
Practice Expense Summary of Recommendation
Facility Direct Inputs

CPT Long Descriptor:

33405 - Replacement, aortic valve, with cardiopulmonary bypass; with prosthetic valve other than homograft or stentless valve

33430 - Replacement, mitral valve, with cardiopulmonary bypass

33533 - Coronary artery bypass, using arterial graft(s); single arterial graft

Global Period: 090 Meeting Date: April 2012

Please provide a brief description of the process used to develop your recommendation and the composition of your Specialty Society Practice Expense Committee:

A reference code must be provided for comparison to the practice expense inputs on your spreadsheet. Please provide a rationale for the selection of reference codes. Comparison Code Rationale:

There are no changes to the practice expense inputs for these three codes

Please describe in detail the clinical activities of your staff:

Received 2 March 2011; revised 29 May 2011; accepted 8 June 2011; online publish-ahead-of-print 22 June 2011

Aims Long-term randomized comparisons of percutaneous coronary intervention (PCI) to coronary artery bypass grafting (CABG) in left main coronary (LM) disease and/or three-vessel disease (3VD) patients have been limited. This analysis compares 3-year outcomes in LM and/or 3VD patients treated with CABG or PCI with TAXUS Express stents.

Methods and results SYNTAX is an 85-centre randomized clinical trial ($n = 1800$). Prospectively screened, consecutive LM and/or 3VD patients were randomized if amenable to equivalent revascularization using either technique; if not, they were entered into a registry. Patients in the randomized cohort will continue to be followed for 5 years. At 3 years, major adverse cardiac and cerebrovascular events [MACCE: death, stroke, myocardial infarction (MI), and repeat revascularization; CABG 20.2% vs. PCI 28.0%, $P < 0.001$], repeat revascularization (10.7 vs. 19.7%, $P < 0.001$), and MI (3.6 vs. 7.1%, $P = 0.002$) were elevated in the PCI arm. Rates of the composite safety endpoint (death/stroke/MI 12.0 vs. 14.1%, $P = 0.21$) and stroke alone (3.4 vs. 2.0%, $P = 0.07$) were not significantly different between treatment groups. Major adverse cardiac and cerebrovascular event rates were not significantly different between arms in the LM subgroup (22.3 vs. 26.8%, $P = 0.20$) but were higher with PCI in the 3VD subgroup (18.8 vs. 28.8%, $P < 0.001$).

Conclusions At 3 years, MACCE was significantly higher in PCI- compared with CABG-treated patients. In patients with less complex disease (low SYNTAX scores for 3VD or low/intermediate terciles for LM patients), PCI is an acceptable revascularization, although longer follow-up is needed to evaluate these two revascularization strategies.

Keywords SYNTAX • Left main • Multivessel disease • PCI • CABG • Stent thrombosis

Introduction

Coronary artery bypass graft surgery (CABG) has been considered the optimum revascularization treatment for patients with *de novo* left main (LM) disease and/or three-vessel disease (3VD). In the past two decades, percutaneous coronary intervention (PCI) has emerged as a possible alternative in patients with complex coronary disease as stent design, procedural technique, and adjunctive medical therapy have improved.[1,2] Recent revisions to revascularization guidelines have reflected these improvements in PCI outcomes for patients with complex coronary disease.[3,4] In general, during the first year after the index procedure, PCI has been found to be as safe as CABG in patients with severe coronary artery disease; however, the rates of retreatment are significantly

Downloaded from http://eurheartj.oxfordjournals.org/ at Duke University on April 4, 2012

higher and PCI failed to show non-inferiority compared with CABG due to increased repeat revascularization.[5,6] Additionally, the occurrence of very late stent thrombosis (ST), although rare, is a concern for patients treated with PCI,[7] whereas the risk of stroke is increased following CABG.[6,8–10]

The overall goal of the SYNTAX trial is to assess the most appropriate revascularization strategy by randomizing patients to either PCI with TAXUS Express stents or CABG. The innovative angiographic SYNTAX score was also developed to help prospectively determine the complexity of the coronary anatomy before embarking on intervention.[11,12] The average number of stents and total stented length implanted in SYNTAX is higher than any other contemporary drug-eluting stent vs. CABG study. The primary endpoint at 1 year was not met; the non-inferiority of PCI compared with CABG was not demonstrated and CABG proved to be superior. After 1 year, no differences were observed in safety outcomes (death, stroke, and MI) between CABG and PCI patients, although the rate of revascularization and overall major adverse cardiac and cerebrovascular events (MACCE) was significantly increased in PCI patients and stroke was significantly increased in CABG patients. The current study reports the 3-year outcomes from the SYNTAX trial.

Methods

Study design, subject selection, and follow-up

The SYNergy between PCI with TAXUS and Cardiac Surgery (SYNTAX) trial is a multinational, randomized (1:1) study comparing clinical outcomes after drug-eluting PCI using the TAXUS Express stent (Boston Scientific, Natick, MA, USA) or CABG in patients with 3VD and/or LM disease. Patients in whom equivalent and comparable revascularization could be achieved by either CABG or PCI (as determined by the cardiothoracic surgeon and interventional cardiologist of the 'Heart Team') were randomized ($n = 1800$; CABG $n = 897$ and PCI $n = 903$). In the LM group, patients could have isolated LM disease or LM plus 1, 2, or 3VD. Patients considered unsuitable for one of the treatment options were enrolled in parallel, nested registries (the PCI registry for CABG-ineligible patients, $n = 198$; CABG registry for PCI-ineligible patients, $n = 1077$). Three-year post-allocation follow-up was assessed by clinic visit; further follow-up will be conducted at 4 (telephone call or clinic visit) and 5 years (clinic visit) post-treatment allocation.

The study protocol was reviewed and approved by an Institutional Review Board/Ethics Committee at each participating site. Before enrolment in the study, each patient provided written informed consent. SYNTAX is registered on the National Institute of Health website (www.clinicaltrials.gov) as NCT00114972. The study design, including details on sample size determination, randomization scheme, and primary endpoint results have previously been described in detail.[6,13]

Definitions

The primary clinical endpoint of SYNTAX was the composite of MACCE [all-cause death, cerebrovascular accident (CVA/stroke), MI, and repeat revascularization] through 12-month post-allocation. Patients were treated with the intention of complete revascularization of all vessels/lesions (reference diameter >1.5 mm, stenosis $\geq 50\%$) identified at the Heart Team conference. Completeness of revascularization was assessed post-procedure by the investigator. All deaths were considered cardiac unless an unequivocal, non-cardiac cause could be established. Cerebrovascular events, or stroke, were defined as focal neurological deficits of central origin lasting >72 h resulting in permanent brain damage or body impairment. The definition of MI was based on previous studies.[14–16] Briefly, MI was defined in relation to intervention status as follows: (i) after allocation but before treatment: Q-wave [new pathological Q-waves in ≥ 2 leads lasting ≥ 0.04 s with creatine kinase-MB (CK-MB) levels elevated above normal] and non-Q-wave MI [elevation of CK levels $>2\times$ the upper limit of normal (ULN) with positive CK-MB or elevation of CK levels to $>2\times$ ULN without new Q-waves if no baseline CK-MB was available]; (ii) <7 days after intervention: new Q-waves and either peak CK-MB/total CK $>10\%$ or plasma level of CK-MB $5\times$ ULN; and (iii) ≥ 7 days after intervention: new Q-waves or peak CK-MB/total CK $>10\%$ or plasma level of CK-MB $5\times$ ULN or plasma level of CK $5\times$ ULN. The CK/CK-MB enzyme levels were obtained and measured by a core laboratory for all randomized patients. Per protocol (symptomatic) graft occlusion (GO) and ST were defined as an acute coronary syndrome with confirmed occlusion within or adjacent to a previously treated graft (GO) or lesion (ST) and/or Q-wave MI in the treated vessel territory within 30 days of the index procedure. Additionally, ST was adjudicated according to the Academic Research Consortium (ARC) definitions as definite or probable and by timing of the event: acute (≤ 1 day post-procedure), subacute (2 to ≤ 30 days), late (>30 to ≤ 365 days), and very late (>365 days).[17] All MACCE, GO, and ST events were adjudicated by an independent, Clinical Events Committee which included a neurologist.

SYNTAX score

Angiograms were scored according to the SYNTAX score algorithm (www.syntaxscore.com)[12] by the Angiographic Core Laboratory (Cardialysis BV, Rotterdam, The Netherlands).

Statistical methods

Analyses were conducted using SAS System Software, Version 8.0 or higher (SAS Institute, Cary, NC, USA). Analyses of the randomized cohort were based on the intent-to-treat principle and in the registries were performed in an as-treated manner. Time-to-event rates are presented for overall 3-year data. Discrete variables are presented as counts and percentages. Differences in the time-to-event curves between the treatment groups were evaluated by a two-sided log-rank test. All tests of interaction were from a χ^2 test from a logistic regression model including the factors of interest and the interaction term. A χ^2 or Fisher's exact test was used, as appropriate, for discrete variables.

Results

The baseline clinical characteristics of the randomized treatment groups were well balanced and have previously been published with clinical outcomes up to 1 year of follow-up.[6] Over 3 years of follow-up, 45 CABG patients withdrew their consent, 12 patients were lost to follow-up and 13 patients had no 3-year clinical visit leading to complete data sets in 92.2% ($n = 827$) of patients in the CABG group. Nine PCI patients withdrew their consent, an additional three PCI patients were lost to follow-up and six patients had no 3-year clinical visit resulting in complete clinical follow-up in 98.0% ($n = 885$) of the PCI group at 3 years (*Figure 1*).

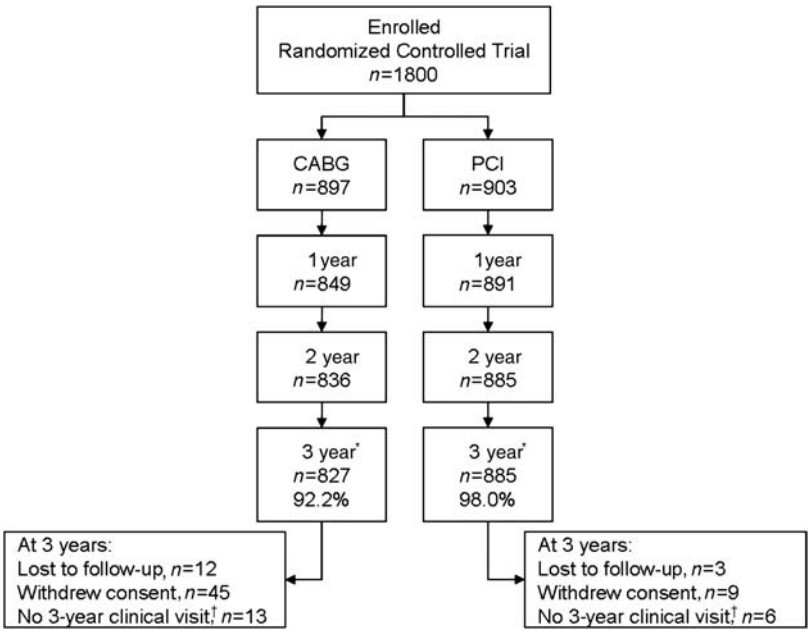

Figure 1 Patient disposition. *Patients evaluable for 3-year major adverse cardiac and cerebrovascular events. †Patients with no 3-year clinical follow-up also includes those patients whose follow-up occurred too early to meet the requirement for adequate follow-up for 3-year major adverse cardiac and cerebrovascular event determination (percutaneous coronary intervention arm $n = 2$). Patients with no 3-year clinical visit have not discontinued their participation in the trial.

Major adverse cardiac and cerebrovascular events at 3-year follow-up in the overall randomized cohort

The rates of MACCE and MACCE components through 3 years, analysed in a time-to-event manner, are presented in *Figures 2* and *3*. Total MACCE through 3 years was significantly higher in the PCI arm compared with the CABG arm (CABG 20.2% vs. PCI 28.0%; $P < 0.001$; *Figure 2A* and *3*). Increased repeat revascularization in the PCI arm was one of the drivers of the difference in MACCE rates between groups at 3 years (CABG 10.7% vs. PCI 19.7%; $P < 0.001$; *Figures 2B* and *3*). The composite safety endpoint of death/stroke/MI was not significantly different between treatment groups 3-year post-randomization (CABG 12.0% vs. PCI 14.1%; $P = 0.21$; *Figures 2C* and *3*). Death from all causes was not different between the treatment groups at 3 years (CABG 6.7% vs. PCI 8.6%; $P = 0.13$, *Figures 2D* and *3*). The cumulative rate of cardiac death was significantly higher at 3 years in the PCI arm (CABG 3.6% vs. PCI 6.0%; $P = 0.02$; *Figure 3*). At 3 years, the incidence of stroke was not significantly different between CABG- (3.4%) and PCI-treated patients (2.0%, $P = 0.07$; *Figures 2E* and *3*). The MI rate at 3 years was 3.6% in the CABG and 7.1% in the PCI cohort ($P = 0.002$; *Figures 2F* and *3*). The rate of post-procedure per protocol GO was 3.2% per patient ($n = 26$) and 1.2% per graft (25/2026) at 3 years, with six patients experiencing a documented GO between the second and third year. The 3-year post-procedure per protocol ST rate was 4.1% per patient ($n = 36$) and 1.2% per stent (45/3715) with four STs occurring more than 2 years after the index procedure. Binary rates of ARC definite/probable ST were 7.4% per patient and 1.6% per stent at 3 years with 23 patients experiencing an ST after the first year of follow-up.

At 3 years, significantly more PCI-randomized patients were receiving dual antiplatelet therapy (DAPT), aspirin therapy, or single antiplatelet therapy compared with patients in the CABG arm (*Table 1*).

Myocardial infarction

A total of 31 CABG-treated ($n = 33$ MI) and 62 PCI-treated ($n = 65$ MI) patients experienced an MI within 3 years of follow-up ($P = 0.002$). The majority of MI occurred periprocedurally in the CABG arm; 4 MIs occurred after randomization but before treatment and an additional 22 occurred within 7 days of the index procedure (see Supplementary material online, *Figure S1*). Fifteen MIs were Q-wave and 11 MIs were non-Q-wave MI (see Supplementary material online, *Figure S1*). In the PCI arm, 2 MIs occurred in patients before and 30 MIs within 7 days following the index treatment (see Supplementary material online, *Figure S1*). The MIs $\geq$7 days after the index procedure in the PCI arm were distributed evenly through the 3 years of follow-up; 13 MIs occurred in the first year of follow-up and 10 MIs occurred in both the second and third year of follow-up. Approximately half of the MIs in the PCI arm were non-Q-wave MI (33/65; see Supplementary material online, *Figure S1*).

Graft occlusion and stent thrombosis

In the CABG arm, MI was a consequence of GO in 6 of 26 CABG-randomized GO patients; each was successfully revascularized. The majority of GO patients in the CABG arm did not experience an MI but did require repeat revascularization (17/26). No events occurred after the GO in three patients. In the PCI arm, 10 of 36 ST patients experienced a fatal MI and 1 patient died after an emergency re-CABG. Eleven patients experienced an MI related to the ST and were successfully revascularized. Fourteen patients (of 36) received revascularization after the ST in the PCI arm. Of the nine patients who experienced a very late ST (>1 year) in the PCI arm, five were receiving DAPT while four were taking aspirin alone. In patients receiving aspirin therapy alone, clopidogrel had been discontinued in two patients 2–4 weeks prior to the ST.

Subgroup analyses

The a priori statistical method was a closed hierarchical testing procedure comparing the overall randomized patient population (including patients with either LM and/or 3VD) first with the 3VD and LM subgroups being compared subsequently only if non-inferiority was concluded for the overall comparison. As non-inferiority was not shown in the overall cohort, specific information for each subgroup should be considered observational and hypothesis-generating only. The 3-year death/stroke/MI, repeat revascularization, and MACCE rates are shown separately for the pre-specified 3VD, LM, and diabetic subgroups of the randomized cohort (*Figure 4*).

There were no significant interactions between LM/3VD status and treatment group for 3-year MACCE or any of the components; the treatment effect of PCI compared with CABG was not significantly different between patients with LM or 3VD. Patients with 3VD treated with PCI experienced significantly more MACCE events, including increased repeat revascularization and combined death/stroke/MI, than those in the CABG arm (*Figure 4A*). Overall mortality (9.5 vs. 5.7%, $P = 0.02$) and cardiac death were significantly increased in 3VD patients treated with PCI (6.2 vs. 2.9%, $P = 0.01$). In the LM cohort, the rates of MACCE and death/stroke/MI were not significantly different in PCI- and CABG-treated patients. The 3-year rate of repeat revascularization was increased in PCI-treated LM patients (*Figure 4B*). There was no difference in all-cause or cardiac death rates in CABG- or PCI-treated patients with LM disease (all-cause: CABG 8.4% vs. PCI 7.3%, $P = 0.64$; cardiac death 4.6 vs. 5.7%, $P = 0.48$). There were no significant interactions observed for the diabetic status and treatment group for 3-year MACCE or any of the components; the treatment effect of PCI compared with CABG was not different based on the diabetic status. The presence of diabetes was associated with increased rates of repeat revascularization and, consequently, MACCE in the PCI arm without increasing the rates of death/stroke/MI over 3 years of follow-up (*Figure 4*). Cardiac death was not significantly different between treatment groups in the subset of diabetic patients (4.8 vs. 8.8%, $P = 0.10$).

Impact of lesion complexity on clinical outcomes

The impact of lesion complexity on clinical outcomes was assessed by examining 3-year patient outcomes relative to their SYNTAX score (*Figure 5*). There was a significant interaction between the SYNTAX score tercile and treatment group for the 3-year outcomes of MACCE, death/stroke/MI, and death ($P = 0.025$, 0.088, and 0.084, respectively). The rates of MACCE and the individual MACCE components were not significantly different in patients with low SYNTAX scores (≤22) treated with either PCI or CABG (*Figure 5A*). In patients with intermediate SYNTAX scores

Downloaded from http://eurheartj.oxfordjournals.org/ at Duke University on April 4, 2012

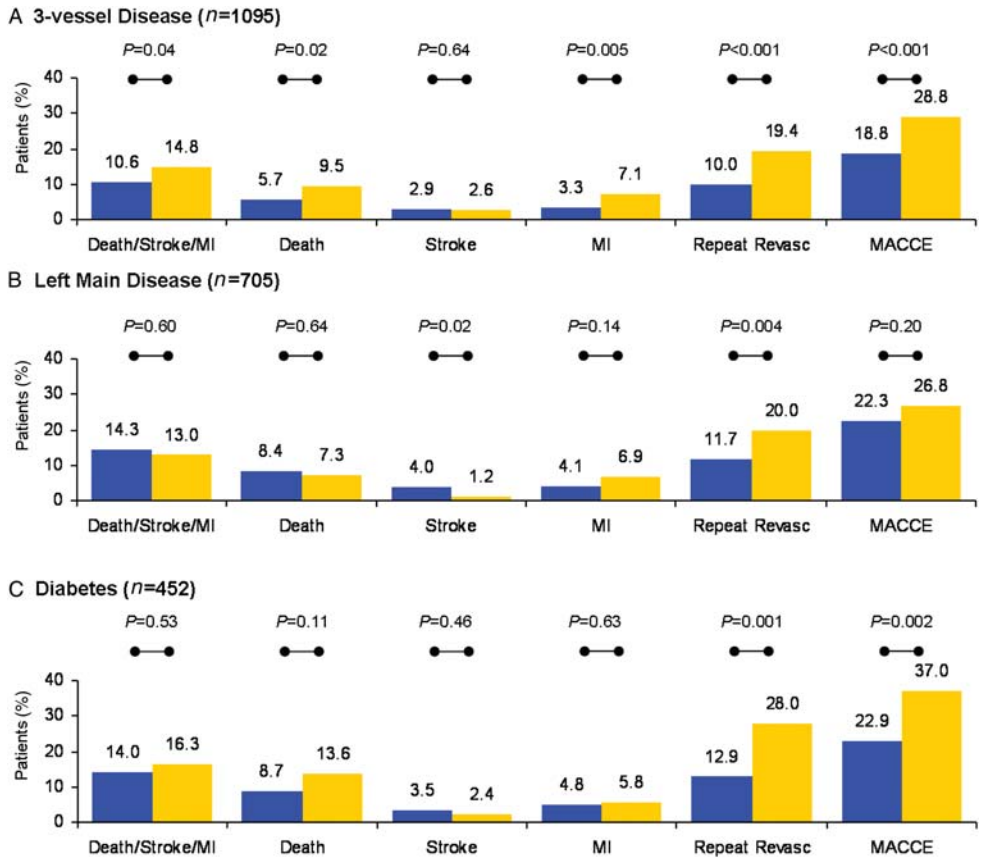

Figure 4 Three-year clinical outcomes according to the treatment group in patients with three-vessel disease, left main disease, or diabetes—death/stroke/myocardial infarction, all-cause death, stroke, myocardial infarction, repeat revascularization (repeat revasc), and major adverse cardiac and cerebrovascular event rates at 3 years in coronary artery bypass grafting (blue bars) or percutaneous coronary intervention-treated (yellow bars) patients with three-vessel (*A*) or left main (*B*) disease or diabetes (*C*). *P*-value from log-rank test.

(23–32), repeat revascularization rates were significantly higher in PCI-treated patients (CABG 10.1% vs. PCI 17.4%, $P = 0.01$), as were MI and MACCE rates (MI: CABG 3.2% vs. PCI 7.6%, $P = 0.02$; MACCE: 18.9 vs. 27.4%, $P = 0.02$; *Figure 5B*). In patients with the most complex anatomical disease (those with SYNTAX scores ≥33), MACCE and its components, apart from stroke, were significantly higher in patients treated with PCI (MACCE: CABG 19.5% vs. PCI 34.1%, $P < 0.001$, *Figure 5C*).

The three-way interaction between the treatment group, LM/3VD status, and SYNTAX score tercile was assessed for 3-year MACCE and components; there were no significant three-way interactions observed.

Patients with 3VD with SYNTAX scores in the lowest tercile exhibited similar MACCE rates between treatment arms (CABG 22.2% vs. PCI 25.8%, $P = 0.45$, *Figure 5D*). In those 3VD patients with intermediate or high SYNTAX scores, the rate of MACCE was significantly increased in favour of CABG (23–32: CABG 16.8% vs. PCI 29.4%, $P = 0.003$; ≥33: CABG 17.9% vs. PCI 31.4%, $P = 0.004$; *Figure 5E* and *F*). Myocardial infarction was significantly higher in the PCI arm of the 3VD intermediate SYNTAX score tercile (3.1 vs. 8.9%, $P = 0.01$). In 3VD patients with SYNTAX score ≥33, mortality (CABG 4.5% vs. PCI 11.1%, $P = 0.03$) and MI (1.9 vs. 7.2%, $P = 0.02$) were significantly higher in the PCI arm.

Major adverse cardiac and cerebrovascular event rates were not significantly different in patients with LM disease who had low or intermediate SYNTAX scores (0–22: CABG 23.0% vs. PCI 18.0%, $P = 0.33$; 23–32: CABG 23.4% vs. PCI 23.4%, $P = 0.90$; *Figure 5G* and *H*). In LM patients with the most complex anatomy (SYNTAX score ≥33), MACCE was significantly increased in PCI-treated patients (CABG 21.2% vs. PCI 37.3%, $P = 0.003$, *Figure 5I*) as was repeat revascularization (9.2 vs. 27.7%, $P < 0.001$). It is of note that the distribution of LM patients with concurrent 3VD was greatest in the 'high' SYNTAX score group in the overall patient population. Additionally, an increased proportion of distal LM lesions were found in the patients with 'high' SYNTAX scores compared with patients in the low and intermediate terciles.

Discussion

Similar to 1-year outcomes in SYNTAX, 3-year MACCE rates were significantly higher in the PCI arm compared with CABG-treated patients. At 3 years, the rate of MI in the PCI arm was significantly

Downloaded from http://eurheartj.oxfordjournals.org/ at Duke University on April 4, 2012

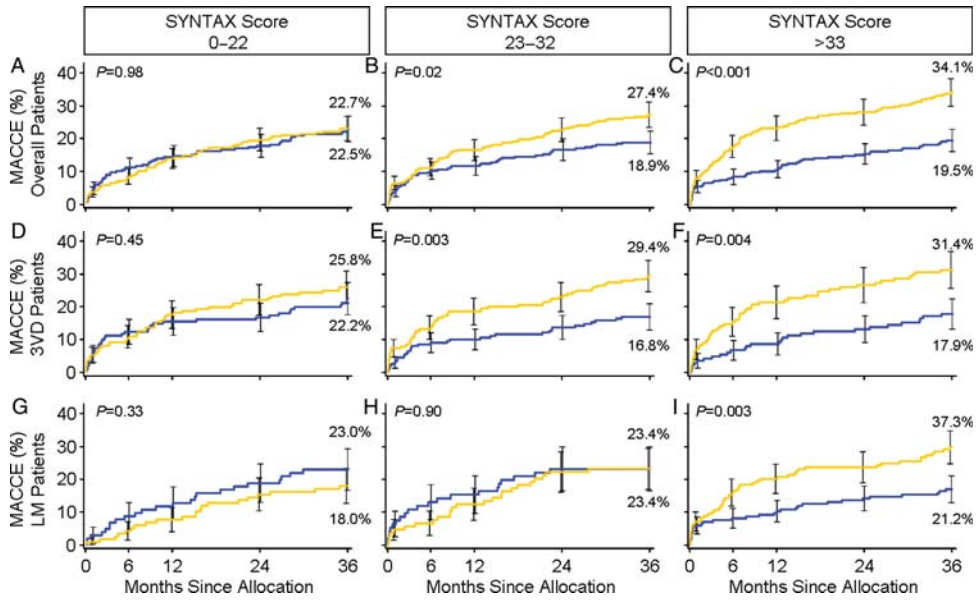

Figure 5 Major adverse cardiac and cerebrovascular event rates according to the subset, treatment group, and SYNTAX score category. Time-to-event curves in the coronary artery bypass grafting (blue line) or percutaneous coronary intervention (yellow line) overall cohorts to 3 years according to the low (0–22, *A*), intermediate (23–32, *B*), or high (≥33, *C*) SYNTAX scores. (*D*–*F*) Major adverse cardiac and cerebrovascular events in three-vessel disease patients with low, intermediate, or high SYNTAX scores, respectively. (*G*–*I*) Major adverse cardiac and cerebrovascular events in patients with left main disease with low, intermediate, or high SYNTAX scores. *P*-value from log-rank test.

increased compared with CABG patients and the difference in stroke rate between treatment arms was not significantly different unlike the outcomes after 1 year of follow-up. SYNTAX patients in the randomized cohort will continue to be followed for 5 years.

The trends in MACCE, death/stroke/MI, all-cause death, and repeat revascularization rates in the overall patient population seen in the first year of follow-up continued through the second and third year, although fewer total events occurred during each additional year of follow-up. Compared with outcomes after 1 year of follow-up, cardiac death was found to be significantly increased in the overall PCI-treated patient population, chiefly in those patients with higher SYNTAX scores at 3 years. The majority of cardiac deaths occurred within the first year of follow-up in both arms; ~40% occurred during the second and third year of follow-up. This difference was cumulative as the interval rates of cardiac death were not significant. Although stroke was significantly increased at 1 year of follow-up for CABG, no difference in stroke was seen during the interval of 1- and 3-year follow-up.

A difference in the MI rate between the two treatment groups was also noted after the report of the first year of follow-up. Two-thirds and one-half of all MIs were periprocedural (occurring within 7 days of the index procedure) in the surgical and PCI cohorts, respectively. The likely cause of the increased MIs in the PCI arm was due to restenosis/further revascularization in these patients with advanced diffuse disease or ST. When compared with CABG patients, MI rates were higher in the 3VD PCI group and not significantly different in the LM PCI cohort.

The clinical consequences of ST were more serious than for patients whose graft occluded. This may be due to the redundancy of patent native arteries available, the presence of collateral vessels in patients undergoing CABG which can be recruited during the process of progressive GO, and to GO being more likely to occur in patients with small target-vessel diameter.[18] The very late ST rate in SYNTAX was higher than in previous studies.[15,19] However, the lesion complexity and, consequently, the average number of stents implanted (4.6 stents per patient) and the average total stented length (86.1 mm) were higher than any other contemporary DES vs. CABG study.[6]

Overall MACCE rates were not significantly different in the pre-specified LM subgroup at 3 years. More PCI patients required reintervention compared with CABG-treated patients between these groups. The current US and European revascularization guidelines assign CABG a IA indication in most patients with 1, 2, or 3VD with low, intermediate, or high SYNTAX scores.[4,20] However, due to positive outcomes from other recent studies of LM patients, these guidelines have upgraded the indication for PCI in the LM artery from a Class III to a Class IIb (ACC/AHA)[4,20] and a Class IIb C to IIa B (ESC-EACTS)[3] indication in patients with isolated LM (ostial or trunk) and with associated 1VD. Additionally, the ESC-EACTS guidelines have also included the treatment of patients with 3VD and low SYNTAX scores as a Class IIa B indication.[3]

Both the presence of multivessel disease and diabetes are known to increase the risks associated with cardiovascular disease. In both of these subgroups, similar to the outcomes

Downloaded from http://eurheartj.oxfordjournals.org/ at Duke University on April 4, 2012

after 1 year of follow-up, the increase in MACCE and revascularization rates was maintained in PCI-treated patients.[6,8,21] Results from the FREEDOM (Future Revascularization Evaluation in Patients with Diabetes Mellitus: Optimal Management of Multivessel Disease)[22] and EXCEL (Evaluation of Xience Prime vs. Coronary Artery Bypass Surgery for Effectiveness of Left Main Revascularization) trials may provide further insight into the optimal treatment for multivessel, diabetic, and LM patients. Particularly, the impact of newer generation stents or stent platforms and the continued improvements in stenting technique will be seen in these trials.

Stratification of the randomized patient population into terciles derived from the baseline anatomical SYNTAX score confirmed the trends in MACCE rates that were found after 1 year of follow-up. Specifically, an intermediate (23–32) or high SYNTAX score (>33) was correlated with an increase in 3-year MACCE rates after percutaneous revascularization compared with surgery. Repeat revascularization, MI, and mortality were significantly higher in 3VD patients with the highest SYNTAX score. Thus, CABG remains the standard for more complex anatomy, whereas PCI in this trial demonstrated similar outcomes to CABG in patients with less complex disease, measured by lower SYNTAX score for 3VD and lower and intermediate scores for LM disease. The SYNTAX score has been successfully applied to other patient groups retrospectively and has shown value in predicting or correlating high anatomical complexity with increased adverse cardiac events making it an effective risk assessment tool.[23–27]

In the SYNTAX trial at 1 year, a significant difference in secondary prevention medical therapy was observed; patients in the surgical cohort were less likely to receive aspirin, thienopyridines, or statins compared with PCI patients. At 3 years, antiplatelet treatment was significantly different between the two treatment arms; patients in the CABG arm were significantly undertreated with single or DAPT than patients in the PCI arm.

Revascularization of all lesions identified at the heart team conference was required to meet the definition of complete revascularization. An anatomic definition of revascularization was used (treatment of lesions with reference diameter >1.5 mm, stenosis ≥50%) when compared with a functional classification (by fractional flow reserve testing). The rates of complete revascularization were 63 and 57% ($P = 0.005$) in the CABG and PCI arms, respectively.[6,13] The rate of complete revascularization in surgically treated patients was low compared with other studies in the literature, in part, due to differing definitions.[16,28,29] In the SYNTAX study, the investigators had to indicate which vessels they intended to graft or stent before actual treatment took place. Comparison with the treatment report revealed whether complete or incomplete revascularization was performed; this is in contrast to other studies where the operators indicated themselves whether they had performed a complete revascularization after the treatment had taken place.

The period of enrolment and index revascularization in SYNTAX occurred during a time of evolving strategies regarding complete revascularization in PCI. The results of FAME and other studies have shown that only those haemodynamically relevant stenoses should be treated unless symptoms of residual myocardial ischaemia arise requiring intervention upon non-culprit vessels.[30,31] Clinical outcomes may differ according to the completeness of revascularization.[32]

Study limitations

The SYNTAX trial was designed to overcome many limitations of previous comparisons of PCI and CABG. In spite of this, there is inadequate statistical power to detect differences in low-frequency events (e.g. stroke, MI) between arms. Additionally, analyses of the LM and 3VD subgroups, although sufficiently powered, can only be considered hypothesis-generating as SYNTAX did not meet its primary endpoint. The analyses of LM or 3VD patients by SYNTAX score were not pre-specified and should be considered exploratory and hypothesis-generating only. A larger number of patients withdrew from the CABG arm post-allocation ($n = 45$) than the PCI arm ($n = 9$), suggesting greater concern on the part of some patients to submit to the more invasive procedure. Sensitivity analyses suggest that the outcomes could have been influenced by non-evaluable patients if they all died. This is unlikely as a total of 57/827 CABG and 77/885 PCI patients who were evaluable died within 3 years of follow-up. The effect of this imbalance was minimized by including all data available up to the point of withdrawal (or lost to follow-up) were included in the analysis set and outcomes were analysed in an intent-to-treat manner. Details related to medical therapy were collected only at 1 and 3 years. Data regarding medical therapy at other intervals is lacking. Finally, the intermediate short (3-year) follow-up time may not provide an accurate estimate of long-term differences in outcomes between the two revascularization methods.

Conclusions

At 3 years, MACCE was increased in PCI patients compared with CABG; no difference was observed in the combined safety endpoint of death, MI, and stroke. Analysis of pre-specified subgroups suggests that for 3VD patients, MACCE, mortality, and the combined safety endpoint of death, MI, and stroke were increased with PCI, whereas for patients with LM disease, there were no significant differences in these outcomes with PCI. In relation to anatomical complexity, patients with less complex coronary anatomy (low SYNTAX scores in 3VD patients or low/intermediate SYNTAX scores in LM patients), PCI can be an acceptable alternative treatment option to CABG. Patients with more complex disease (3VD patients with intermediate/high SYNTAX scores and LM patients with high scores) have an increased risk of an MACCE event with PCI and CABG is the preferred treatment option.

A 57-year-old male patient was treated in the intensive therapy unit for pneumonia and new-onset atrial fibrillation. He had a ventriculoatrial (VA) shunt since childhood which was placed for hydrocephalus. He had no other medical problems and had been lost to follow-up. Transthoracic echocardiography (*Panel A*) revealed significant calcific tricuspid stenosis, a dilated right atrium (RA), an unusually large right atrial appendage (RAA), and an aneurysmal interatrial septum. Subsequent transoesophageal echocardiography (*Panels B–D*) confirmed severe tricuspid stenosis with a mean gradient of 5 mmHg and turbulent transvalvular Doppler flow (*Panel C*). Furthermore, a mobile mass was noted at the tip of the VA shunt (*Panels B–D*, arrow) that was best visualized on the bicaval view (*Panel D*, arrow). This was most likely the result of an inflammatory response and thrombus. There was minimal tricuspid regurgitation and no pulmonary hypertension. Blood and urine cultures proved negative and empirical antibiotic therapy was given for 2 weeks. The patient made a good recovery and was discharged with anticoagulation and beta-blockers. At 6-monthly follow-up, he was found to be asymptomatic. Right heart complications can occur years after VA shunt placement. If symptomatic tricuspid stenosis develops, percutaneous valvuloplasty or surgical valve replacement should be considered. Surveillance of patients with VA shunts is currently poorly defined. There is also a paucity of published literature regarding the same. Our case illustrates the need for long-term clinical and echocardiographic follow-up in patients with VA shunts.

ADULT CARDIAC INTENSITY REFERENCE TABLE

CPT	long descriptor	2012 Intensity
33412	Replacement, aortic valve; with transventricular aortic annulus enlargement (Konno procedure)	122
33413	Replacement, aortic valve; by translocation of autologous pulmonary valve with allograft replacement of pulmonary valve (Ross procedure)	122
33863	Ascending aorta graft, with cardiopulmonary bypass, with aortic root replacement using valved conduit and coronary reconstruction (eg, Bentall)	121
33545	Repair of postinfarction ventricular septal defect, with or without myocardial resection	121
35536	Bypass graft, with vein; splenorenal	120
33427	Valvuloplasty, mitral valve, with cardiopulmonary bypass; radical reconstruction, with or without ring	119
33945	Heart transplant, with or without recipient cardiectomy	117
33548	Surgical ventricular restoration procedure, includes prosthetic patch, when performed (eg, ventricular remodeling, SVR, SAVER, Dor procedures)	117
33530	Reoperation, coronary artery bypass procedure or valve procedure, more than 1 month after original operation (List separately in addition to code for primary procedure)	115
33877	Repair of thoracoabdominal aortic aneurysm with graft, with or without cardiopulmonary bypass	114
33406	Replacement, aortic valve, with cardiopulmonary bypass; with allograft valve (freehand)	114
33411	Replacement, aortic valve; with aortic annulus enlargement, noncoronary sinus	114
33860	Ascending aorta graft, with cardiopulmonary bypass, includes valve suspension, when performed	114
33410	Replacement, aortic valve, with cardiopulmonary bypass; with stentless tissue valve	113
33542	Myocardial resection (eg, ventricular aneurysmectomy)	112
33426	Valvuloplasty, mitral valve, with cardiopulmonary bypass; with prosthetic ring	111
33425	Valvuloplasty, mitral valve, with cardiopulmonary bypass;	108
35560	Bypass graft, with vein; aortorenal	107
33400	Valvuloplasty, aortic valve; open, with cardiopulmonary bypass	106
33460	Valvectomy, tricuspid valve, with cardiopulmonary bypass	105
33475	Replacement, pulmonary valve	102
33465	Replacement, tricuspid valve, with cardiopulmonary bypass	102
33464	Valvuloplasty, tricuspid valve; with ring insertion	101
33463	Valvuloplasty, tricuspid valve; without ring insertion	100
33141	Transmyocardial laser revascularization, by thoracotomy; performed at the time of other open cardiac procedure(s) (List separately in addition to code for primary procedure)	97
33510	Coronary artery bypass, vein only; single coronary venous graft	97
33474	Valvotomy, pulmonary valve, open heart; with cardiopulmonary bypass	94
33641	Repair atrial septal defect, secundum, with cardiopulmonary bypass, with or without patch	94
35518	Bypass graft, with vein; axillary-axillary	91
33140	Transmyocardial laser revascularization, by thoracotomy; (separate procedure)	90
44950	Appendectomy;	78
35301	Thromboendarterectomy, including patch graft, if performed; carotid, vertebral, subclavian, by neck incision	77
35656	Bypass graft, with other than vein; femoral-popliteal	75
33208	Insertion of new or replacement of permanent pacemaker with transvenous electrode(s); atrial and ventricular	61
99245	Office consultation for a new or established patient, which requires these 3 key components: A comprehensive history; A comprehensive examination; and Medical decision making of high complexity. Counseling and/or coordination of care with other providers	52

Adherence of Catheterization Laboratory Cardiologists to American College of Cardiology/American Heart Association Guidelines for Percutaneous Coronary Interventions and Coronary Artery Bypass Graft Surgery

What Happens in Actual Practice?

Edward L. Hannan, PhD; Michael J. Racz, PhD; Jeffrey Gold, MD; Kimberly Cozzens, MA; Nicholas J. Stamato, MD; Tia Powell, MD; Mary Hibberd, MD; Gary Walford, MD

Background—The American College of Cardiology and the American Heart Association have issued guidelines for the use of coronary artery bypass graft surgery (CABG) and percutaneous coronary interventions (PCI) for many years, but little is known about the impact of these evidence-based guidelines on referral decisions.

Methods and Results—A cardiac catheterization laboratory database used by 19 hospitals in New York State was used to identify treatment (CABG surgery, PCI, medical treatment, or nothing) recommended by the catheterization laboratory cardiologist for patients undergoing catheterization with asymptomatic/mild angina, stable angina, and unstable angina/non–ST-elevation myocardial infarction between January 1, 2005, and August 31, 2007. The recommended treatment was compared with indications for these patients based on American College of Cardiology/American Heart Association guidelines. Of the 16 142 patients undergoing catheterization who were found to have coronary artery disease, the catheterization laboratory cardiologist was the final source of recommendation for 10 333 patients (64%). Of these 10 333 patients, 13% had indications for CABG surgery, 59% for PCI, and 17% for both CABG surgery and PCI. Of the patients who had indications for CABG surgery, 53% were recommended for CABG and 34% for PCI. Of the patients with indications for PCI, 94% were recommended for PCI. For the patients who had indications for both CABG surgery and PCI, 93% were recommended for PCI and 5% for CABG surgery. Catheterization laboratory cardiologists in hospitals with PCI capability were more likely to recommend patients for PCI than hospitals in which only catheterization was performed.

Conclusions—Patients with coronary artery disease receive more recommendations for PCI and fewer recommendations for CABG surgery than indicated in the American College of Cardiology/American Heart Association guidelines. (***Circulation*. 2010;121:267-275.**)

Key Words: AHA/ACC guidelines ■ procedure indications ■ percutaneous coronary intervention ■ coronary artery bypass surgery

The American College of Cardiology (ACC) and the American Heart Association (AHA) jointly publish guidelines to inform practicing clinicians of the appropriate indications for a variety of treatments, including percutaneous coronary angioplasty (PCI) and coronary artery bypass graft (CABG) surgery[1–3] for patients with coronary artery disease (CAD). These guidelines were created for the purpose of helping clinicians use evidence-based medicine and expert opinions to determine whether the benefits outweigh the risks for these procedures. They include categories in which patients can be placed on the basis of factors such as type of angina, ventricular function, number of coronary vessels diseased, results of noninvasive tests for ischemia, and various other factors.

Editorial see p 194
Clinical Perspective on p 275

Recent studies have examined the conformance with guidelines among patients undergoing PCI[4,5] or CABG surgery[6] and have demonstrated a direct relationship between

Downloaded from circ.ahajournals.org at Duke University--Durham on January 16, 2010

guidelines adherence and better outcomes.[4,5] However, these studies examined conformance to guidelines among patients who received only 1 of the 2 major procedures for CAD and did not examine the concomitant use of PCI and CABG surgery guidelines to make referral choices. This is of particular interest because guidelines exist for both PCI and CABG surgery, and these 2 procedures are competing options for patients with CAD, especially multivessel disease. Furthermore, many of the referring cardiologists who perform the diagnostic procedure that leads to a referral decision (cardiac catheterization) also perform PCI, and PCI is frequently performed during the same catheterization laboratory visit as the cardiac catheterization without seeking a multidisciplinary consultation.

The purpose of the present study was to use a cardiac catheterization database in New York State to compare referral decisions with ACC/AHA guidelines to examine the extent to which cardiac catheterization laboratory cardiologists adhered to guidelines when they were the final source of the recommendation. The study also examined whether adherence rates changed substantially after guidelines were revised by the ACC/AHA and whether adherence to guidelines was impacted by whether the hospital in which the catheterization was performed was certified by the New York State Department of Health to perform PCI and/or CABG surgery.

Methods

Database

Data were obtained from New York State's Cardiac Diagnostic Catheterization Database $(CD)^2$, a voluntary data system in New York maintained by the New York State Department of Health. The data set was developed to capture indications for CABG surgery and PCI with the published ACC/AHA guidelines. These include PCI guidelines published in 2001 and 2005 and CABG surgery guidelines published in 2004.[1–3] Data elements used in the study to identify indications for PCI and CABG surgery were the vessels diseased, including left main disease and proximal left anterior descending coronary artery; Canadian Cardiovascular Society class; whether the anatomy was suitable for PCI and/or surgery; ejection fraction and presence of congestive heart failure; ST-segment elevation myocardial infarction, non–ST-segment elevation myocardial infarction, and unstable angina, if present; diabetes; shock, and hemodynamic instability; area of viable myocardium at risk; and stress test results.

Completeness of data reporting was monitored by matching $(CD)^2$ to New York's acute care hospital discharge database, the Statewide Planning and Research Cooperative System (SPARCS), and New York's PCI Registry (PCIRS, the Percutaneous Coronary Interventions Reporting System) and identifying cases reported with a diagnostic catheterization in those databases that were not reported to $(CD)^2$. Hospitals were required to provide data for those missing cases. In addition, missing or invalid data elements were returned to hospitals for review and correction on an ongoing basis.

With regard to recommendations, the data set indicates whether the catheterization laboratory cardiologist recommended CABG surgery, PCI, medical treatment, or no treatment. The database also indicates whether the final recommendation was anticipated to come from another source (eg, consulting cardiologists or surgeon), but it does not include the final recommendation for those cases.

Patients and Hospitals

A total of 19 hospitals were included in the study. Eight of these hospitals are full-service hospitals that provide PCI and CABG surgery in addition to cardiac catheterization. The other 11 provided only catheterization at the outset of the study, but 5 added PCI during the study. In subsequent analyses that compared types of hospitals, these 5 were classified accordingly in the time frames before and after they added PCI.

Patients in the study included a subset of patients in the 19 study hospitals undergoing cardiac catheterization between January 1, 2005, and December 31, 2007, who had CAD, had not undergone previous revascularization, and were not experiencing an ST-segment elevation myocardial infarction. Patients were excluded if information needed to determine whether a procedure was indicated or should be recommended was missing (n=504), if there were deferred recommendations (n=124) or multiple recommendations (n=872), or if the source of final recommendation was anyone other than the catheterization laboratory cardiologist (n=4813). Recommendations from other sources, deferred recommendation, and multiple recommendations were excluded because the nature of the final recommendation was unknown at the time the data were gathered. Thus, with the exclusion of cases with missing data, there were 16 142 patients who were found to have CAD, and the cardiac catheterization laboratory cardiologist was the final source of recommendation for 10 333 (64%). These patients are the subjects of the present study.

End Points

End points in the study were determinations of whether each patient met the ACC/AHA indications for CABG surgery, PCI, neither, or both and the recommendations made by the catheterization laboratory cardiologist for each patient. The recommendations for each patient were categorized as CABG surgery, PCI, medical treatment, or no treatment.

Statistical Analysis

First, the percentages of patients in each of the 4 categories of indications for the 2 procedures (indicated for PCI and CABG surgery, indicated for PCI only, indicated for CABG surgery only, or indicated for neither procedure) were calculated for each of a variety of patient characteristics (demographics, source of admission, ventricular function, coronary vessel disease, suitability of coronary anatomy for each intervention, presence of angina, previous cardiac procedures, previous myocardial infarction, and several comorbidities). Patients in each of the 4 categories of indications were classified according to whether they were recommended for PCI, CABG surgery, or neither procedure. Percentages of patients who were recommended for each procedure but for whom the procedure was not indicated and percentages of patients who had indications for a procedure but for whom it was not recommended were noted and described. The term "indicated" was first defined in such a way that class I criteria (evidence and/or general agreement that the procedure is effective) and class IIa criteria (the weight of opinion/evidence is in favor of usefulness or efficacy) were treated equally as "adherence to guidelines." If 1 procedure was judged to be class I and the other procedure was judged to be class IIa for a given patient, the patient was said to be indicated for both procedures.

A second set of analyses was then conducted in which meeting class I criteria took precedence over meeting class IIa criteria. That is, if 1 procedure (either CABG surgery or PCI) was judged to be class I and the other procedure (eg, PCI) was judged to be class IIa for a given patient, the patient was said to be indicated for CABG surgery but not for PCI. Subsequent analyses were all variations of the first interpretation of indications, whereby a patient with a class I criterion for 1 procedure and a class IIa criterion for another procedure was regarded as indicated for both procedures.

One supplemental set of analyses compared adherence to guidelines before and after the publication of new PCI guidelines in 2005 to determine whether there was a difference in adherence after the updated guidelines were published. April 1, 2006, was used as the time the new guidelines were incorporated in the present study, to give clinicians time to have read and implemented the 2005 guidelines. The 2004 CABG guidelines were used for the entire time period of the present study for identification of indications for CABG surgery. The analyses described above were repeated for each of the

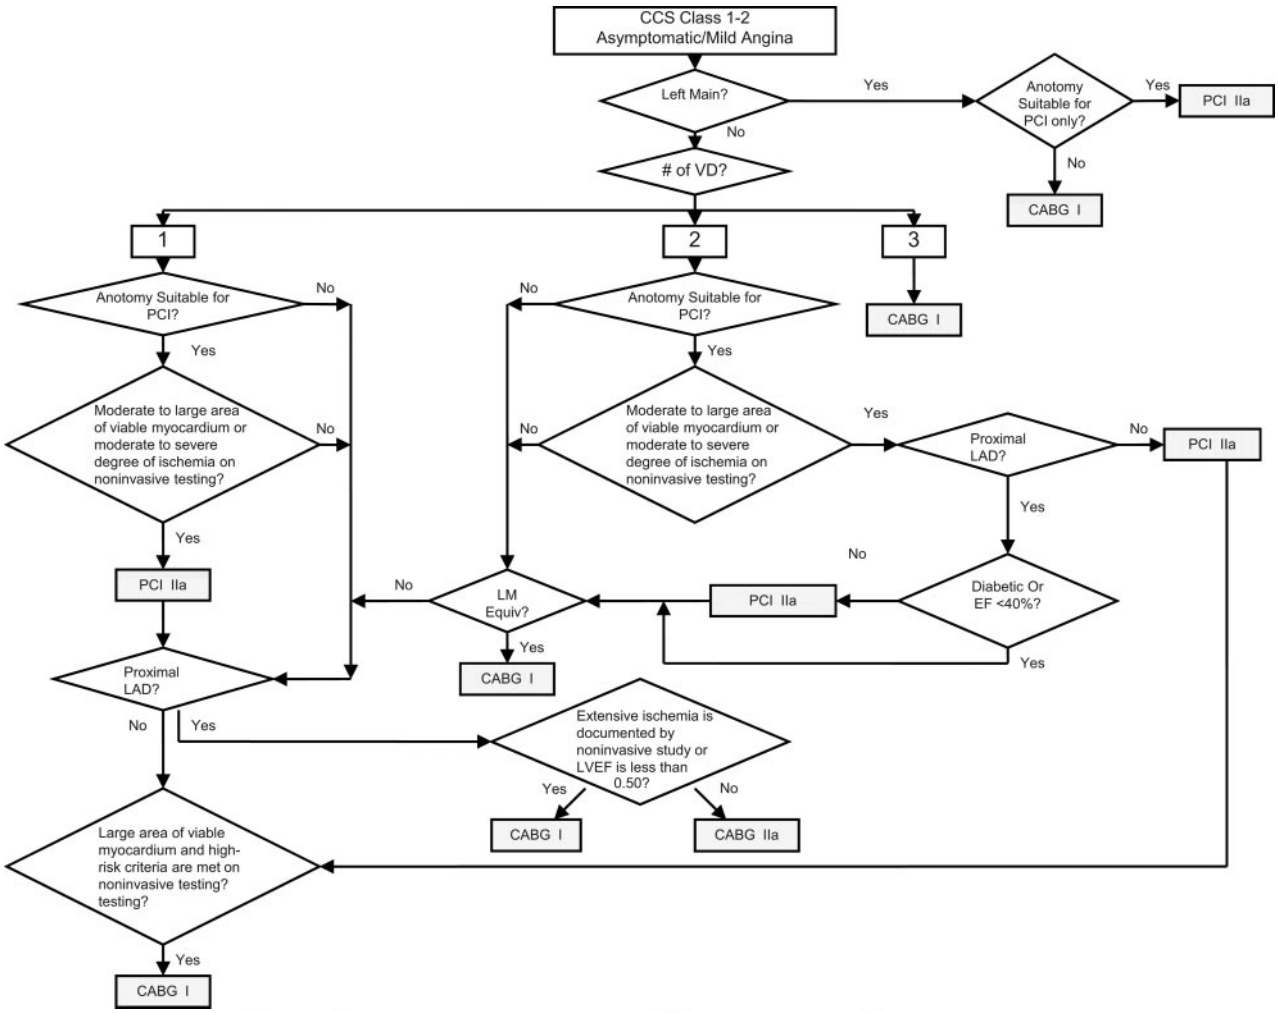

Figure 1. 2005 ACC/AHA indications (class I and IIa) for asymptomatic/mild angina. CCS indicates Canadian Cardiovascular Society; VD, diseased vessels; LAD, left anterior descending coronary artery; LM, left main; EF, ejection fraction; and LVEF, left ventricular ejection fraction.

3 types of hospitals (catheterization-only hospitals that are not certified by the New York State Department of Health to perform PCI, those certified to perform catheterization and elective PCI, and full-service hospitals that are certified to perform both PCI and CABG surgery) to compare their levels of adherence to guidelines.

Results

Flow charts that demonstrate who is indicated for CABG surgery and PCI at levels I and IIa for each of the 3 major groups of patients (asymptomatic/mild angina, stable angina, unstable angina/non–ST-elevation myocardial infarction) in the study are presented in Figures 1 to 3. Of the 16 142 patients undergoing catheterization with complete data who were found to have CAD, the catheterization laboratory cardiologist was the final source of recommendation for 10 333 patients (64%). Of these 10 333 patients, 1337 (12.9%) were indicated for CABG surgery, 6051 (58.6%) were indicated for PCI, 1722 (16.7%) were indicated for CABG surgery and PCI, and 1223 (11.8%) had CAD but were indicated for neither CABG surgery nor PCI (Table 1). A total of 9.6% of the patients were recommended for CABG surgery compared with 77.3% for PCI and 12.7% for medical treatment.

Patients who were indicated for CABG surgery were recommended for it 53% of the time (712 patients). Thirty-four percent of patients (455) with indications for CABG surgery were recommended for PCI, and 12% were recommended for medical therapy. Of the patients with indications for PCI, 94% were recommended for it, 2% were recommended for CABG surgery, and 4% were recommended for medical treatment. For the 17% of patients with indications for both CABG surgery and PCI, 93% were recommended for PCI, 5% were recommended for CABG surgery, and 2% were recommended for medical therapy (Table 1). For the patients with CAD who were not indicated for CABG surgery or PCI (12% of all patients), 71% were recommended for medical treatment, 21% were recommended for PCI, and 6% were recommended for CABG surgery.

Although 53% of the patients with indications for CABG surgery were recommended for CABG, there was a wide variation in the percentage recommended for CABG depending on patients' clinical presentations. In general, CABG was recommended 58% of the time when it was a class I indication (and PCI was indicated at a class below class IIa), but CABG was recommended only 7% of the time when it

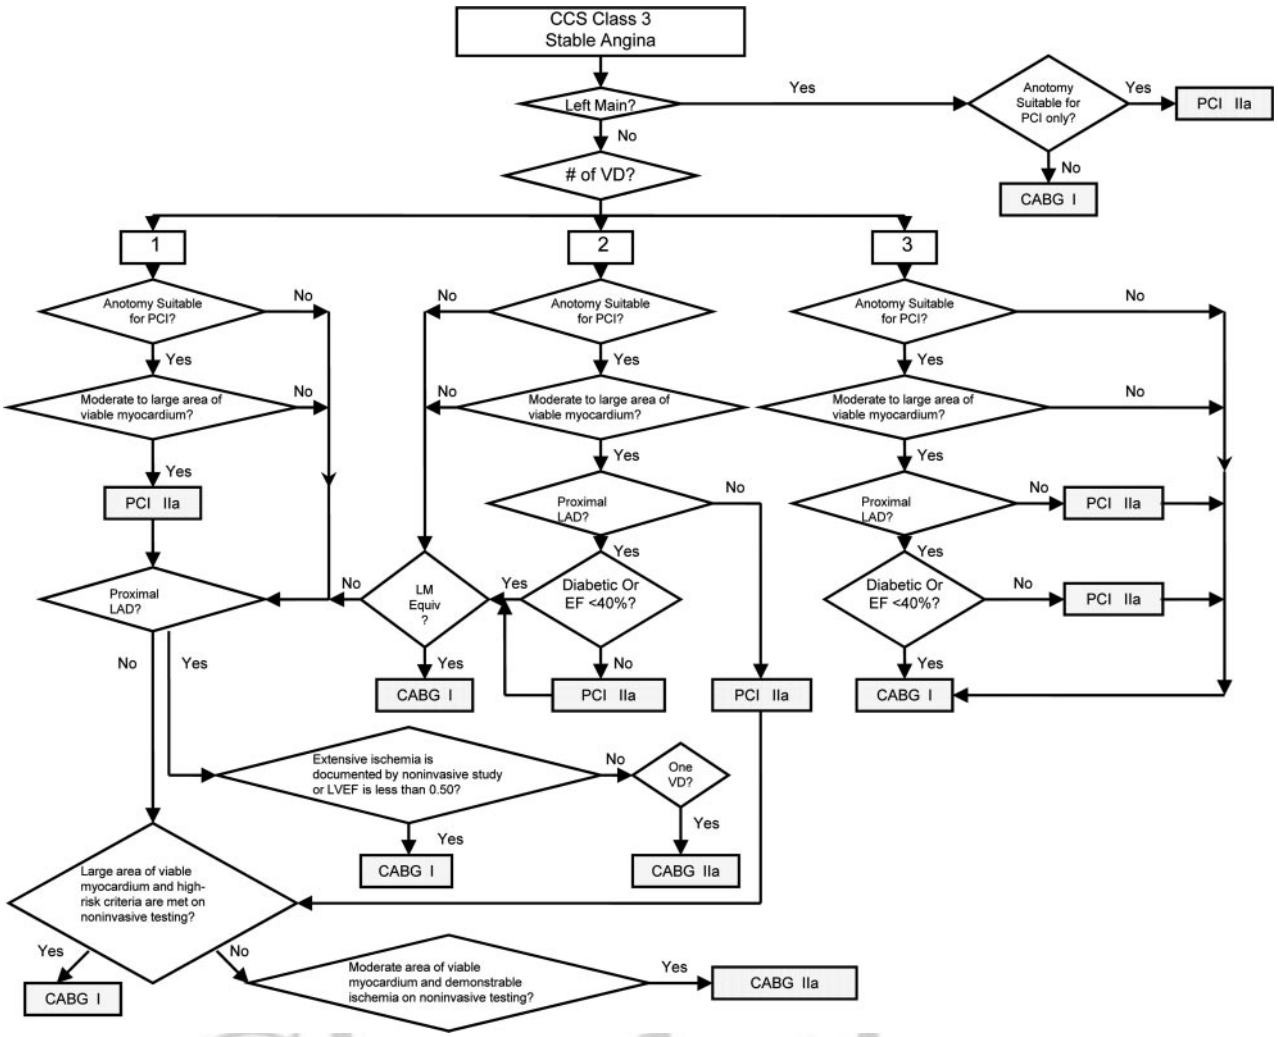

Figure 2. 2005 ACC/AHA indications (class I and IIa) for stable angina. CCS indicates Canadian Cardiovascular Society; VD, diseased vessels; LAD, left anterior descending coronary artery; LM, left main; EF, ejection fraction; and LVEF, left ventricular ejection fraction.

was a class IIa indication (and PCI was indicated at a class below class IIa). The percentage of the time that CABG was recommended for subgroups of CABG-indicated patients was highest at 90% (26 of 29 cases) for patients with stable angina and significant left main disease and 80% (118 of 147) for patients with unstable angina/non–ST-elevation myocardial infarction who had ongoing ischemia, for whom PCI is not optimal or possible. The percentage was lowest at 4% (4 of 96) for patients with unstable angina/non–ST-elevation myocardial infarction who had proximal left anterior descending coronary artery stenosis with 1- or 2-vessel disease.

Table 2 reflects changes in Table 1 when patients who met class I ACC/AHA criteria for 1 procedure and class IIa criteria for the other procedure (invariably CABG and PCI, respectively) were judged as being indicated for the class I procedure. The major change compared with Table 1 was that the percentage of patients indicated only for CABG surgery who were recommended for PCI rose from 34% to 46%, with a concomitant decrease in the percentage of patients indicated only for CABG surgery who were recommended for CABG from 53% to 43%. When the patients in Table 1 (in which class I and class IIa criteria were regarded as equally indicated) were subdivided into 2 groups based on whether the patients underwent cardiac catheterization before or after April 1, 2006 (ie, before or after referring physicians were able to use the 2005 ACC/AHA guidelines), the percentage of patients not indicated for revascularization who were recommended for PCI dropped from 33% to 12% (Table 3).

Table 4 subdivides the results in Table 1 into 3 groups: Patients who underwent cardiac catheterization in hospitals that perform catheterization but no PCI (catheterization-only hospitals), hospitals certified to perform catheterization and elective PCI (elective PCI hospitals), and hospitals certified to perform catheterization, elective PCI, and CABG (full-service PCI hospitals). The percentage of patients who were indicated for CABG who were recommended for PCI rose from 17% in catheterization-only hospitals to 22% in elective PCI hospitals to 43% in full PCI hospitals. These same trends occurred among patients who were indicated for both procedures (a rise in recommendations for PCI from 81% to 85% to 96%). Patients in catheterization-only hospitals appeared to be less sick with regard to angina type (less unstable angina and lower Canadian Cardiovascular Society class), so this was a possible explanation to the extent that nonindicated

Downloaded from circ.ahajournals.org at Duke University--Durham on January 16, 2010

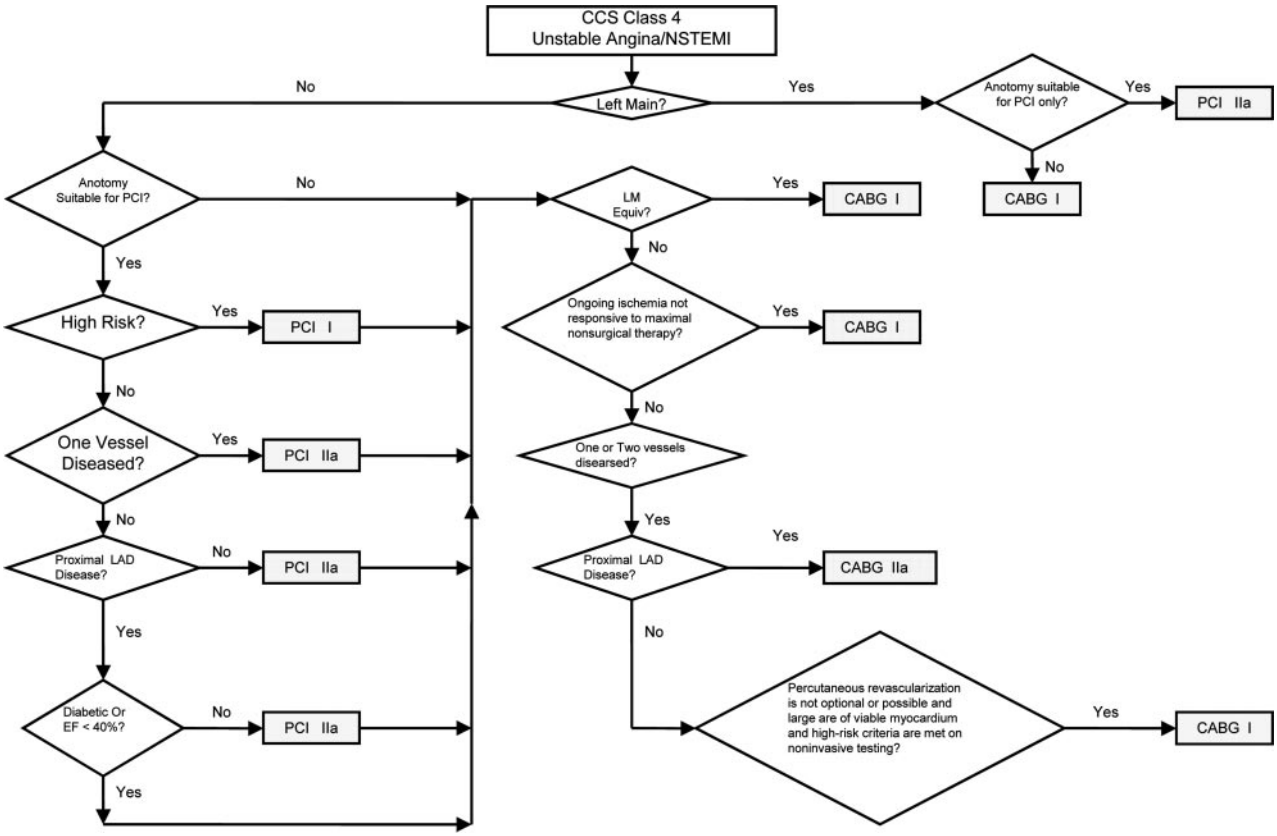

Figure 3. 2005 ACC/AHA indications (class I and IIa) for unstable angina/non–ST-elevation myocardial infarction. CCS indicates Canadian Cardiovascular Society; NSTEMI, non–ST-elevation myocardial infarction; LM, left main; LAD, left anterior descending coronary artery; and EF, ejection fraction.

patients were recommended disproportionately for different clinical presentations.

The variation in the percentage of patients in individual hospitals who were indicated for CABG but recommended for PCI was quite wide, with a range from 4% to 91% among hospitals with at least 50 patients indicated for CABG. However, the mean of 34% in Table 1 was not driven by a few large hospitals.

For all but 2 hospitals, the percentage of patients indicated for both CABG and PCI who were recommended for PCI was >80%. For those 2 hospitals, 57% (74 of 129) and 63% (30 of 48) of such patients were recommended for PCI.

Of the 7984 patients recommended for PCI, 6941 patients were in hospitals with PCI capability. A total of 6399 (92.2%) of these patients underwent ad hoc PCI (PCI in the same catheterization laboratory visit as their cardiac catheterization).

Discussion

The ACC and the AHA periodically have developed guidelines for the use of CABG surgery and PCI for patients with coronary heart disease. Surprisingly few studies have been conducted to determine the extent to which referring physicians use these guidelines or any guidelines in clinical practice. Anderson et al[5] used data from the ACC's National Cardiovascular Data Registry from January 2001 to March 2004 to demonstrate that 64% of the PCI patients were class I, 21% were class IIa, 7% were class IIb, and 8% were class III. In addition, clinical success (<25% residual stenosis without myocardial infarction, same-admission CABG surgery, or death) rates were directly related to indication class and varied from 92.8% for class I to 85.5% for class III.[5]

O'Connor et al[6] used data from the Northern New England Cardiovascular Disease Study Group to determine the con-

cordance of patients undergoing CABG surgery in northern New England with the 2004 ACC/AHA guideline update for CABG surgery.[3] They found that 87.7% of the procedures performed were class I, 8.4% were class IIa, 2.5% were class IIb, and 1.4% were class III.

Guidelines other than those developed by the ACC/AHA were used in a few earlier studies. Leape et al[7] used guidelines developed by RAND[8] to examine the appropriateness of use of CABG surgery in New York State in 1990. They concluded that nearly 91% of the procedures were appropriate, 7% were uncertain, and 2.4% were inappropriate.[7] McGlynn et al[9] demonstrated that the rates of inappropriateness of coronary angiography and CABG surgery were low in both Canada and New York State. Hilborne et al[10] used RAND criteria to conclude that in New York State in 1990, 58% of percutaneous transluminal coronary angioplasty (PTCA, the previous term for PCI) cases were appropriate, with 38% uncertain and 4% inappropriate.

Although most studies have examined the overuse of cardiac procedures, some studies have examined underuse by applying RAND appropriateness criteria for coronary angiography to determine the percentages of those patients who received indicated procedures. Hannan et al[11] found that 52% of angiography patients for whom CABG surgery was found to be appropriate received it within 3 months, and there were significant differences by race. Leape et al[12] found that 74% of patients in New York City in 1992 who met the RAND appropriateness criteria for revascularization received either CABG surgery or PTCA (PCI).

Most of the studies referenced above are relatively old; all but 2 used now-outdated RAND criteria rather than ACC/AHA criteria; none looked at both potential overuse and underuse of procedures; and none looked at the interface of CABG surgery and PCI with regard to whether 1 of the 2 procedures was used or recommended when the other was indicated by guidelines. This last point is particularly important, because many recent studies have examined outcomes according to choice of revascularization. These studies include studies that compared drug-eluting and bare-metal stents.[13–15] Other studies have compared outcomes for CABG surgery and PCI and generally have found CABG surgery outcomes to be superior.[16–18] Furthermore, some recent studies have compared medical treatment favorably with PCI for patients with stable coronary disease.[19,20] In light of all of these recent findings, it is important to determine who is being referred for various treatment options and to learn how

these referral patterns compare with the latest ACC/AHA guidelines and the latest studies that compare outcomes for competing interventions.

The present study demonstrates that for 64% of patients undergoing catheterization who were found to have CAD, the source of the final recommendations for treatment was the cardiac catheterization laboratory cardiologist. Of the subset of these patients who were indicated for CABG surgery, 53% were recommended for CABG and 34% for PCI. Of the patients indicated for PCI, 94% were recommended for PCI. For the patients who were indicated for both CABG surgery and PCI, 93% were recommended for PCI and 5% for CABG surgery.

Thus, patients received more recommendations for PCI and fewer for CABG surgery than were indicated. The tendency to recommend PCI for patients who were either indicated for CABG surgery or indicated for both procedures was more accentuated in hospitals with PCI capability. In summary, these findings suggest that catheterization laboratory cardiologists make final recommendations relatively frequently and that these recommendations are frequently for PCI despite the fact that CABG surgery or both CABG and PCI are indicated. The finding that PCI appears to be recommended more often than indicated is particularly important because as noted above, some recent studies have found CABG surgery outcomes to be better than PCI outcomes for patients with multivessel disease,[16–18] and other studies have found that medical treatment compares favorably with PCI for patients with stable coronary disease.[19,20]

There are a few caveats to the present study. First, we had to translate the ACC/AHA indications for CABG and PCI into a flowchart that incorporates both of them simultaneously, and there may be disagreement on the way this was done. For instance, we developed indications by taking the ACC/AHA guidelines in the order in which they were presented for each level, and different interpretations could result if the order were changed. In addition, we did not have access to information relative to whether the patient was already receiving medical therapy, which was a factor in defining some indications. Indications for PCI would be reduced if the patient was not undergoing medical therapy, so the impact of having this data element would be to increase the number of recommendations for PCI among patients for whom it was not indicated. However, it would have been valuable to have had information on the extent of medical therapy in the study.

Nonetheless, we believe our interpretations are essentially the same as those made in recent studies,[4,6] and we have developed the flow charts presented in the appendices so that the logic is transparent. We believe these flowcharts are the first attempt to integrate ACC/AHA indications for both CABG surgery and PCI, and we are hopeful they can be used as a first cut for revision or by referring physicians to determine potential indications for patients with CAD.

Recent commentary on ACC/AHA clinical practice guidelines reminds us that clinical practice guidelines are intended to be only general guides for practice, and there may be extenuating circumstances that may lead a provider or patient to opt for a different decision.[21] In addition, the CABG and PCI guidelines were developed at different times, by different people, in different ways, and no effort appears to have been

Downloaded from circ.ahajournals.org at Duke University--Durham on January 16, 2010

made to standardize them so referring physicians could use them simultaneously to make recommendations. Consequently, another major reason for the lack of concordance between guidelines and recommendations may be that referring physicians were unable to determine what should have been recommended according to the guidelines. The ACC and AHA in conjunction with other professional organizations have recently published appropriateness criteria for coronary revascularization that were developed to serve as a supplement to the ACC/AHA guideline documents.[22] Although that document does not distinguish between appropriateness of PCI and CABG surgery for all patients (because for some groups, the appropriateness rating applies only to "revascularization"), it does address the appropriateness of both procedures in the same document, and it would be interesting to apply the methodology used in the present study to these new appropriateness criteria.

Furthermore, the results may not be representative of all patients undergoing cardiac catheterization in New York. A total of 19 of the 75 to 80 hospitals that provided cardiac catheterization in New York volunteered to be part of the study. For 2005, the earliest year of the study, there were 10 hospitals in the study, and hospitals were gradually added until all 19 were participating. Over the course of the study period, 5 catheterization-only hospitals began providing elective PCI, and these hospitals were treated in the analyses according to their status at the time.

We did not always know whether the treatment that was recommended was actually received. However, we were able to determine whether patients recommended by the catheterization laboratory cardiologist for PCI in a hospital with PCI capability underwent ad hoc PCI (PCI in the same laboratory visit as the cardiac catheterization). As noted in the Results, most patients recommended for PCI in the present study (6941 of 7984) were in hospitals with PCI capability, and more than 92% of these patients underwent ad hoc PCI. This demonstrates that patients recommended for PCI did receive the procedure, and they received it with seemingly little multidisciplinary input or deliberation.

Although an examination of the patients recommended for medical therapy who were indicated for revascularization provides some measure of underuse of revascularization procedures, it is likely that because cardiac catheterization is the driver for revascularization procedures, the majority of underuse would be among patients who never received cardiac catheterization. In conclusion, the results of the present study suggest that multidisciplinary input before final treatment recommendations should be promoted to improve concordance with professional guidelines.

Acknowledgments

The authors would like to thank New York State's Cardiac Advisory Committee for their encouragement and support of this study; and Paula Waselauskas, Cynthia Johnson, Erika Ihara, and the cardiac catheterization laboratories of the participating hospitals for their tireless efforts to ensure the timeliness, completeness, and accuracy of the data submitted.

CLINICAL PERSPECTIVE

Although the American College of Cardiology and the American Heart Association have issued guidelines for the use of coronary artery bypass graft surgery (CABG) and percutaneous coronary interventions (PCI) for many years, little is known about the impact of these evidence-based guidelines on referral decisions. A cardiac catheterization laboratory database used by 19 hospitals in New York State was used to identify treatment (CABG surgery, PCI, medical treatment, or nothing) recommended by the catheterization laboratory cardiologist for patients undergoing catheterization with asymptomatic/mild angina, stable angina, and unstable angina/non–ST-elevation myocardial infarction between January 1, 2005, and August 31, 2007. The recommended treatment was compared with indications for these patients based on American College of Cardiology/American Heart Association guidelines. Findings were that of the 16 142 patients undergoing catheterization who were found to have coronary artery disease, the catheterization laboratory cardiologist was the final source of recommendation for 10 333 patients (64%). Of these cases, 13% were indicated for CABG surgery, 59% for PCI, and 17% for CABG surgery and PCI. Of the patients who were indicated for CABG surgery, 53% were recommended for CABG and 34% for PCI. Of the patients indicated for PCI, 94% were recommended for PCI. For the patients who were indicated for both CABG surgery and PCI, 93% were recommended for PCI and 5% for CABG surgery. In conclusion, patients with coronary artery disease receive more recommendations for PCI and fewer recommendations for CABG surgery than are indicated in the American College of Cardiology/American Heart Association guidelines.

Abstract

The American College of Cardiology Foundation (ACCF), Society for Cardiovascular Angiography and Interventions, Society of Thoracic Surgeons, and the American Association for Thoracic Surgery, along with key specialty and subspecialty societies, conducted an update of the appropriate use criteria (AUC) for coronary revascularization frequently considered. In the initial document, 180 clinical scenarios were developed to mimic patient presentations encountered in everyday practice and included information on symptom status, extent of medical therapy, risk level as assessed by noninvasive testing, and coronary anatomy. This update provides a reassessment of clinical scenarios the writing group felt to be affected by significant changes in the medical literature or gaps from prior criteria. The methodology used in this update is similar to the initial document, and the definition of appropriateness was unchanged. The technical panel scored the clinical scenarios on a scale of 1 to 9. Scores of 7 to 9 indicate that revascularization is considered appropriate and likely to improve patients' health outcomes or survival. Scores of 1 to 3 indicate revascularization is

Downloaded from content.onlinejacc.org by Peter Smith on February 11, 2012

considered inappropriate and unlikely to improve health outcomes or survival. Scores in the mid-range (4 to 6) indicate a clinical scenario for which the likelihood that coronary revascularization will improve health outcomes or survival is uncertain.

In general, as seen with the prior AUC, the use of coronary revascularization for patients with acute coronary syndromes and combinations of significant symptoms and/or ischemia is appropriate. In contrast, revascularization of asymptomatic patients or patients with low-risk findings on noninvasive testing and minimal medical therapy are viewed less favorably. The technical panel felt that based on recent studies, coronary artery bypass grafting remains an appropriate method of revascularization for patients with high burden of coronary artery disease (CAD). Additionally, percutaneous coronary intervention may have a role in revascularization of patients with high burden of CAD. The primary objective of the appropriate use criteria is to improve physician decision making and patient education regarding expected benefits from revascularization and to guide future research.

Preface

The American College of Cardiology Foundation (ACCF), in collaboration with the Society for Cardiovascular Angiography and Interventions (SCAI), the Society of Thoracic Surgeons (STS), the American Association for Thoracic Surgery (AATS), and other societies, developed and published in 2009 appropriate use criteria (AUC) for certain clinical scenarios in which coronary revascularization could be used in an effort to address the rational use of coronary revascularization in the delivery of high-quality care. This document is the first focused update of the original document and includes new literature published since the original document and gaps noted during implementation.

The publication of AUC reflects one of several ongoing efforts by the ACCF and its partners to assist clinicians caring for patients with cardiovascular diseases and in support of high-quality cardiovascular care. The ACCF/American Heart Association (AHA) clinical practice guidelines provide a foundation for summarizing evidence-based cardiovascular care and, when evidence is lacking, provide expert consensus opinion that is approved in review by the ACCF and AHA. However, in many areas, variability remains in the use of cardiovascular procedures, raising questions of over- or underuse. The AUC provide a practical standard upon which to assess and better understand variability.

We are grateful to the technical panel and its chair, Frederick A. Masoudi, MD, MSPH, FACC, FAHA, a professional group with a wide range of skills and insights, for their thoughtful and thorough deliberation of the merits of coronary revascularization for various clinical scenarios. We would also like to thank the parent AUC Task Force and the ACCF staff, Joseph M. Allen and Lea Binder, for their exceptionally skilled support in the generation of this document.

Manesh R. Patel, MD, FACC
Chair, Coronary Revascularization Writing Group

Michael J. Wolk, MD, MACC
Chair, Appropriate Use Criteria Task Force

Introduction

This report is a focused update of the AUC for coronary revascularization published in 2009 (1). The increasing prevalence of coronary artery disease (CAD), continued advances in surgical and percutaneous techniques for revascularization and concomitant medical therapy for CAD, and the costs of revascularization have resulted in heightened interest regarding the appropriate use of coronary revascularization. Clinicians, payers, and patients are interested in the specific benefits of revascularization. Inappropriate revascularization may be harmful to patients and generate unwarranted costs to the healthcare system, whereas appropriate revascularization procedures can improve patients' clinical outcomes.

As in the original AUC document, the same classification scheme with ratings of appropriate, uncertain, and inappropriate was used. The uncertain category can cause confusion in the interpretation of the AUC and can imply several meanings within its definition. First, the rating of uncertain is used when pertinent literature is either not available or when true discrepancies exist. Second, it is impossible to include every relevant piece of clinical information (e.g., age, sex, diabetes) in the individual clinical scenarios. Attempting to do that may result in an unmanageable number of clinical scenarios and thus compromise the usefulness of the AUC in daily practice. The practice of medicine is full of uncertainties that require a thoughtful clinician to use his or her best judgment about each patient to reach decisions about management. Therefore, a rating of uncertain may be assigned by members of the technical panel if clinical information not provided might affect their individual rating, causing a shift into either the appropriate or inappropriate category.

A rating of uncertain means simply what the name implies, and depending on additional factors, it can be appropriate or inappropriate to perform revascularization. The writing group emphasizes that uncertain indications are not inappropriate. Rather, they reflect clinical scenarios that are reasonable for performing revascularization, but additional clinical factors should be considered or further research is needed to more definitively define the benefits of treatment for patients.

All prior AUC publications have reflected an ongoing effort to critically and systematically create, review, and categorize the appropriateness of certain cardiovascular

Downloaded from content.onlinejacc.org by Peter Smith on February 11, 2012

ARTICLE IN PRESS

diagnostic tests, whereas the AUC for coronary revascularization remains the only document addressing treatment. The writing group and technical panel members for this update are identical to the initial AUC (with only 1 exception) and comprised of members from relevant professional societies including both practicing interventional cardiologists and a cardiothoracic surgeon.

For the majority of clinical scenarios, the technical panel only considered the appropriate use of revascularization irrespective of whether this was accomplished by percutaneous coronary intervention (PCI) or coronary artery bypass graft surgery (CABG). However, in a select subgroup of clinical scenarios in which revascularization is generally considered appropriate, the appropriateness of PCI and CABG, individually, was considered. In this subgroup, it was recognized that a focused update could be necessary following publication of the SYNTAX (Synergy Between PCI With TAXUS and Cardiac Surgery) trial (2). Therefore, in this update, the writing group identified 4 indications possibly affected by results of the SYNTAX trial for reexamination. The writing group also split 2 of the indications to represent levels of disease burden, recognizing, however, that the ability to reproducibly quantify the SYNTAX score in routine clinical practice has challenges. Also in this subgroup, the variables of diabetes and depressed left ventricular function were included in the initial AUC, but these were combined for the update because all indications with these variables were rated the same in the previous scores by the technical panel.

In addition, since the publication of the original document, efforts to implement data collection protocols related to the AUC indications identified a gap in the clinical scenarios related to lower-risk unstable angina/non–ST-segment elevation myocardial infarction (UA/NSTEMI) patients and asymptomatic patients with 1- or 2-vessel CAD not involving the proximal left anterior descending artery (LAD) in whom no noninvasive testing had been performed. Although limited new evidence is available for these patient populations since publication, the writing group developed indications to address these previous omissions.

Methods

A detailed description of the methods used for rating the selected clinical indications is found in a previous publication, "ACCF Proposed Method for Evaluating the Appropriateness of Cardiovascular Imaging" (3). Briefly, this process combines evidence-based medicine and practice experience by engaging a technical panel in a modified Delphi exercise. The technical panel is created from nominations given by multiple relevant professional societies and provider-led organizations as well as from health policy and payer communities. To preserve objectivity, technical panels are created so as to not include a majority of individuals whose livelihood is tied to the technology under evaluation.

In making its appropriate use determinations, the technical panel is provided with summaries of the relevant evidence from the medical literature and practice guidelines. Panelists are first asked individually, and then collectively, to assess the benefits and risks of a test or procedure in the context of the potential benefits to patients' outcomes and an implicit understanding of the associated resource use and costs. After the rating process, the final appropriate use ratings are summarized using an established rigorous methodology (4).

Indication Development

Appropriate use criteria are based on current understanding of the technical capabilities and potential patient benefits of the procedures examined. The AUC are also developed to identify common clinical scenarios—but they cannot possibly include every conceivable patient presentation. The term *indication* is used interchangeably with *clinical scenario* in the document for brevity and does not imply that a procedure should necessarily be performed. Some patients seen in clinical practice are not represented in these appropriate use criteria or have additional extenuating features that would alter the appropriateness of treatment as compared with the clinical scenarios presented. Additionally, although AUC indications and ratings are shaped by the guidelines, the AUC often contain more detailed clinical scenarios than the more generalized situations covered in clinical practice guidelines, and thus, subtle differences between these 2 guidance tools may be possible. To minimize this possibility, the coronary revascularization criteria were updated in conjunction with members of the ACCF/AHA PCI and CABG revascularization guideline committees.

Appropriate use criteria are intended to assist patients and clinicians, but are not intended to diminish the acknowledged difficulty or uncertainty of clinical decision making and cannot act as substitutes for sound clinical judgment and practice experience. Rather, the aim of these criteria is to allow assessment of utilization patterns for a test or procedure. Comparing utilization patterns across a large subset of provider's patients can allow for an assessment of a provider's management strategies with those of his/her peers. The ACCF and its collaborators believe that an ongoing review of one's practice using these criteria will help guide a more effective, efficient, and equitable allocation of healthcare resources, and ultimately, better patient outcomes.

The indications went through external review by multisociety and specialty representation for the 2009 document. Because of the narrow focus, the indications were not sent for external review for this update.

Scope of Indications

As previously described, the indications for coronary revascularization were developed considering the following common variables:

Downloaded from content.onlinejacc.org by Peter Smith on February 11, 2012

ARTICLE IN PRESS

a. The clinical presentation (e.g., acute coronary syndrome, stable angina);
b. Severity of angina (asymptomatic, Canadian Cardiovascular Society [CCS] Class I, II, III, or IV);
c. Extent of ischemia on noninvasive testing and the presence or absence of other prognostic factors, such as congestive heart failure, depressed left ventricular function, or diabetes;
d. Extent of medical therapy; and
e. Extent of anatomic disease (1-, 2-, 3-vessel disease, with or without proximal LAD or left main coronary disease).

The clinical scenarios developed include coronary anatomy, as this is the focus of much of the previous literature on coronary revascularization. However, the writing group recognizes that for everyday patient care, symptom status, ischemic burden, and level of medical therapy often play a critical role in decision making even before the coronary anatomy has been defined by angiography. It is important to note that the indications focus on revascularization, percutaneous or surgical, and do not address diagnostic catheterization or coronary angiography; these criteria are currently under development.

Technical Panel Selection

Stakeholders were given the opportunity to participate in the AUC process by submitting nominees from their organizations through a call for nominations announced in the summer of 2006. From this list of nominees, the AUC Task Force and writing group selected technical panel members to ensure an appropriate balance with respect to expertise. The 17-member technical panel was composed of 4 interventional cardiologists, 4 cardiovascular surgeons, 8 members representing noninterventional cardiologists, other physicians who treat patients with cardiovascular disease, health outcome researchers, and 1 medical officer from a health plan. For the update of the AUC for coronary revascularization, the same technical panelists (with 1 exception) from the original document published in 2009 were reconvened to rerate the 15 clinical scenarios included in the focused update.

Rating Process and Scoring

The technical panel members first rated indications independently. Then, the technical panel participated in 2 conferences calls for a discussion of each indication. After the discussion, panelists independently provided their final scores for each indication. Each panelist had equal weight in producing the final result for the indications and was not forced into consensus. For each indication, the median numerical score was determined and then assigned to an appropriate use category.

For the conference calls, each technical panelist received a personalized rating form that indicated his/her rating for each indication and the distribution of de-identified ratings of other members of the panel. In addition, the moderator received a summary rating form with similar information (including panelist identification), along with other statistics reflecting the level of agreement among technical panel members. The level of agreement among panelists, as defined by RAND, was analyzed for each indication based on the BIOMED rule for a panel of 14 to 16 (a simplified RAND method for determining disagreement) (4). Per the BIOMED definition, agreement was defined as an indication where 4 or fewer panelists' ratings fell outside the 3-point region containing the median score. Disagreement was defined as a situation where at least 5 panelists' ratings fell in both the appropriate and the inappropriate categories. Because the technical panel had 17 representatives, which exceeded the 16 addressed in this rule, an additional level of agreement analysis as described by RAND was performed that examined the interpercentile range compared with interpercentile range adjusted for symmetry (4). This information was used by the moderator to guide the technical panel's discussion by highlighting areas of differences among the panelists.

In developing these appropriate use criteria for coronary revascularization, the technical panel was asked to assess whether coronary revascularization for each indication was appropriate, uncertain, or inappropriate using the following definition of appropriate use:

Coronary revascularization is appropriate when the expected benefits, in terms of survival or health outcomes (symptoms, functional status, and/or quality of life) exceed the expected negative consequences of the procedure.

The technical panel scored each indication on a scale from 1 to 9 as follows:

Median Score 7 to 9

Appropriate procedure for specific indication (procedure **is** generally acceptable and **is** a reasonable approach for the indication).

Median Score 4 to 6

Uncertain for specific indication (procedure **may** be generally acceptable and **may** be a reasonable approach for the indication). Uncertainty implies that more research and/or patient information is needed to classify the indication definitively.

Median Score 1 to 3

Inappropriate procedure for that indication (procedure **is not** generally acceptable and **is not** a reasonable approach for the indication).

The division of these scores into 3 levels of appropriateness is somewhat arbitrary, and the numeric designations should be viewed as a continuum. Further, there is diversity in clinical opinion for particular clinical scenarios, such that scores in the intermediate level of appropriateness should be labeled uncertain, because critical patient or research data may be lacking or discordant. This designation serves as a prompt to the field to carry out definitive research investigations whenever possible. It is anticipated that the AUC reports will continue to be revised as further data are

Downloaded from content.onlinejacc.org by Peter Smith on February 11, 2012

generated and information from the implementation of the criteria is accumulated.

To prevent bias in the scoring process, care was taken in providing objective, nonbiased information, including guidelines and key references, to the technical panel.

General Assumptions

Specific assumptions are provided that were considered by the technical panel in rating the relevant clinical scenarios for the appropriate use of revascularization:

1. Each clinical scenario includes the patient's clinical status/symptom complex, ischemic burden by noninvasive functional testing when presented, burden of coronary atherosclerosis as determined by angiography, and intensity of medical therapy in the determination of the appropriate use of coronary revascularization.
2. Assume coronary angiography has been performed when these findings are presented in the indications. The technical panel should rate the appropriateness of revascularization based upon the clinical features and coronary findings, and not the appropriateness of diagnostic coronary angiography.
3. Assume left main coronary artery stenosis (greater than or equal to 50% luminal diameter narrowing) or proximal LAD stenosis (greater than or equal to 70% luminal diameter narrowing) is not present unless specifically noted. Assume no other significant coronary artery stenoses are present except those noted in the clinical scenario.
4. The clinical scenarios should be rated based on the published literature regarding the risks and benefits of percutaneous and surgical coronary revascularization. Note that specific patient groups not well represented in the literature are not presented in the current clinical scenarios. However, the writing group recognizes that decisions about coronary artery revascularization in such patients are frequently required. Examples of such patients include those with end-stage renal disease or advanced age.
5. Clinical outcome is related to the extent of coronary artery disease (Table A1) (5). Based on this observation and clinical guideline recommendations regarding "borderline" angiographic stenosis (50% to 60%) in epicardial (non-left main) locations, a significant coronary stenosis for the purpose of the clinical scenarios is defined as:
   - Greater than or equal to 70% luminal diameter narrowing, by visual assessment, of an epicardial stenosis measured in the "worst view" angiographic projection.
   - Greater than or equal to 50% luminal diameter narrowing, by visual assessment, of a left main stenosis measured in the "worst view" angiographic projection.

Table A1. CAD Prognostic Index

Extent of CAD	Prognostic Weight (0–100)	5-Year Survival Rate (%)*
1-vessel disease, 75%	23	93
>1-vessel disease, 50% to 74%	23	93
1-vessel disease, ≥95%	32	91
2-vessel disease	37	88
2-vessel disease, both ≥95%	42	86
1-vessel disease, ≥95% proximal LAD	48	83
2-vessel disease, ≥95% LAD	48	83
2-vessel disease, ≥95% proximal LAD	56	79
3-vessel disease	56	79
3-vessel disease, ≥95% in at least 1	63	73
3-vessel disease, 75% proximal LAD	67	67
3-vessel disease, ≥95% proximal LAD	74	59

*Assuming medical treatment only. Reprinted with permission from Califf et al. (5).
CAD = coronary artery disease; LAD = left anterior descending coronary artery.

6. All patients are receiving standard care, including guideline-based risk factor modification for primary or secondary prevention in cardiovascular patients unless specifically noted (6–10).
7. Despite the best efforts of the clinician, all patients may not achieve target goals for risk factor modification. However, a plan of care to address risk factors is assumed to be occurring in patients represented in the indications. For patients with chronic stable angina, the writing group recognizes that there is a wide variance in the medical therapy for angina. The specific definition of maximal anti-ischemic medical therapy is presented in the definition section and includes the use of 2 or more antianginal medications.
8. Operators performing percutaneous or surgical revascularization have appropriate clinical training and experience and have satisfactory outcomes as assessed by quality assurance monitoring (11–13).
9. Revascularization by either percutaneous or surgical methods is performed in a manner consistent with established standards of care (11–13).
10. In the clinical scenarios, no unusual extenuating circumstances exist (such as inability to comply with antiplatelet agents, do not resuscitate status, patient unwilling to consider revascularization, technically not feasible to perform revascularization, or comorbidities likely to markedly increase procedural risk substantially) unless specifically noted.

Definitions

A complete set of definitions of terms used throughout the clinical scenarios is listed in Appendix A. These definitions were provided to and discussed with the technical panel prior to the rating of indications.

Downloaded from content.onlinejacc.org by Peter Smith on February 11, 2012

Maximal Anti-Ischemic Medical Therapy

As previously stated, the indications assume that patients are receiving risk factor modification according to guideline-based recommendations. For the purposes of the clinical scenarios presented, **maximal antianginal medical therapy is defined as the use of at least 2 classes of therapies to reduce anginal symptoms**.

Stress Testing and Risk of Findings on Noninvasive Testing

Stress testing is commonly used for both diagnosis and risk stratification of patients with coronary artery disease. Using criteria defined for traditional exercise stress tests (14):

Low-risk stress test findings: associated with a cardiac mortality of less than 1% per year

Intermediate-risk stress test findings: associated with a 1% to 3% per year cardiac mortality

High-risk stress test findings: associated with a greater than 3% per year cardiac mortality

Examples of findings from noninvasive studies and their associated level of risk for cardiac mortality are presented in Table A2 (13). As noted in the footnote to this table, for certain low-risk findings, there may be additional findings that alter the assessment of risk, but these relationships have not been well studied. Implicit in these risk definitions is a measure of the amount of myocardium at risk, or ischemic myocardium. For the purpose of the indications for coronary revascularization, stress test findings are presented by these risk criteria. For patients without stress test findings, please refer to the note below on invasive methods of determining hemodynamic significance. Assume that when prior testing (including an imaging procedure) is referenced in an indication, the testing was performed correctly and with sufficient quality so as to produce a meaningful and accurate result within the limits of the test performance.

For the purposes of the clinical scenarios in this document, patients with both typical and atypical angina are classified by the feature of the CCS grading system presented below. Patients with noncardiac chest pain should be considered to be asymptomatic.

Grading of Angina Pectoris by the Canadian Cardiovascular Society Classification System (15)

Class I: Ordinary physical activity does not cause angina, such as walking, climbing stairs. Angina occurs with strenuous, rapid, or prolonged exertion at work or recreation.

Class II: Slight limitation of ordinary activity. Angina occurs on walking more than 2 blocks on the level and climbing more than 1 flight of ordinary stairs at a normal pace and in normal condition.

Class III: Marked limitations of ordinary physical activity. Angina occurs on walking 1 or 2 blocks on the level and climbing 1 flight of stairs in normal conditions and at a normal pace.

Class IV: Inability to carry on any physical activity without discomfort—anginal symptoms may be present at rest.

High-Risk Features for Short-Term Risk of Death or Nonfatal MI for UA/NSTEMI (16)

At least 1 of the following:

- History—accelerating tempo of ischemic symptoms in preceding 48 hours
- Character of pain—prolonged ongoing (greater than 20 minutes) rest pain
- Clinical findings
  - Pulmonary edema, most likely due to ischemia
  - New or worsening mitral regurgitation murmur
  - S_3 or new/worsening rales
  - Hypotension, bradycardia, tachycardia
  - Age greater than 75 years
- Electrocardiogram
  - Angina at rest with transient ST-segment changes greater than 0.5 mm
  - Bundle-branch block, new or presumed new
  - Sustained ventricular tachycardia
- Cardiac marker
  - Elevated cardiac TnT, TnI, or CK-MB (e.g., TnT or TnI greater than 0.1 ng per mL)

TIMI Risk Score—for Patients With Suspected ACS (17)

Variables (1 point each)

- Age ≥65 years
- ≥3 risk factors (hypertension, diabetes mellitus, family history, lipids, smoking)
- Known CAD (stenosis ≥50%)
- Aspirin use in past 7 days
- Severe angina (≥2 episodes within 24 hours)
- ST-segment deviation ≥0.5 mm
- Elevated cardiac markers

Risk of death or ischemic event through 14 days

- Low: 0–2 (<8.3% event rate)
- Intermediate: 3–4 (<19.3% event rate)
- High: 5–7 (41% event rate)

Abbreviations

CABG = coronary artery bypass grafting
CAD = coronary artery disease
CCS = Canadian Cardiovascular Society
CTO = chronic total occlusion
FFR = fractional flow reserve
HF = heart failure

Table A. Focused Update: New or Revised Indications

	Indication	Appropriate Use Score (1–9)	
	Patients With Acute Coronary Syndromes		
9.	• UA/NSTEMI and low-risk features (e.g., TIMI score ≤2) for short-term risk of death or nonfatal MI • Revascularization of the presumed culprit artery	U (6)	
10.	• UA/NSTEMI and intermediate-risk features (e.g., TIMI score 3–4) for short-term risk of death or nonfatal MI • Revascularization of the presumed culprit artery	A (8)	
	Patients Without Prior Bypass Surgery Asymptomatic		
20.	• One- or 2-vessel CAD without involvement of proximal LAD • No noninvasive testing performed	I (3)	
	Method of Revascularization: Multivessel CAD, CCS Angina Greater Than or Equal to Class III, and/or Evidence of Intermediate- to High-Risk Findings on Noninvasive Testing		
		PCI	CABG
62.	• Two-vessel CAD with proximal LAD stenosis	A (7)	A (8)
63.	• Three-vessel CAD with low CAD burden (i.e., 3 focal stenoses, low SYNTAX score)	A (7)	A (9)
64.	• Three-vessel CAD with intermediate to high CAD burden (i.e., multiple diffuse lesions, presence of CTO, or high SYNTAX score)	U (4)	A (9)
65.	• Isolated left main stenosis	U (6)	A (9)
66.	• Left main stenosis and additional CAD with low CAD burden (i.e., 1- to 2-vessel additional involvement, low SYNTAX score)	U (5)	A (9)
67.	• Left main stenosis and additional CAD with intermediate to high CAD burden (i.e., 3-vessel involvement, presence of CTO, or high SYNTAX score)	I (3)	A (9)

A = appropriate; CAD = coronary artery disease; CCS = Canadian Cardiovascular Society; CTO = chronic total occlusion; I = inappropriate; LAD = left anterior descending coronary artery; MI = myocardial infarction; SYNTAX = Synergy Between PCI With TAXUS and Cardiac Surgery; TIMI = Thrombolysis In Myocardial Infarction; U = uncertain; UA/NSTEMI = unstable angina/non–ST-segment elevation myocardial infarction.

IVUS = intravascular ultrasound
LAD = left anterior descending artery
LIMA = left internal mammary artery
LV = left ventricular
LVEF = left ventricular ejection fraction
MI = myocardial infarction
PCI = percutaneous coronary intervention
STEMI = ST-segment elevation myocardial infarction
TIMI = Thrombolysis In Myocardial Infarction
UA/NSTEMI = unstable angina/non–ST-segment elevation myocardial infarction

Results of Updated Ratings

The writing group evaluated the previous 180 clinical scenarios and identified those where reevaluation, expansion, or consolidation was felt necessary (Table A). Nine of the 15 updated indications met the definition of agreement as described above. There were no ratings where the technical panel held such opposing viewpoints that the technical panel's votes were determined to be in "disagreement" as defined by the strict RAND definitions and described previously in the Methods section.

As the majority of the original clinical scenarios and ratings were not rerated in this update, Table A represents the focused update indications. In addition, the entire list of 171 clinical scenarios and their appropriateness scores are shown below in Tables 1, 2, 3, and 4. Figures 1, 2, 3, 4, and 5 demonstrate gradients in appropriate use rating by increasingly severe symptom status and ischemic risk, and by the method of revascularization. These are also presented in a format similar to the original document. In addition to the changes reflected in Table A, the fractional flow reserve (FFR) cut point was updated from 0.75 to 0.80 in indication 22 to reflect new literature since the publication of the original document and to maintain consistency with guidelines (18).

Coronary Revascularization Appropriate Use Criteria (by Indication)

Table 1. Patients With Acute Coronary Syndromes

	Indication	Appropriate Use Score (1–9)
1.	• STEMI • Less than or equal to 12 hours from onset of symptoms • Revascularization of the culprit artery	A (9)
2.	• STEMI • Onset of symptoms within the prior 12 to 24 hours • Severe HF, persistent ischemic symptoms, or hemodynamic or electrical instability present	A (9)
3.	• STEMI • Greater than 12 hours from symptom onset • Asymptomatic; no hemodynamic instability and no electrical instability	I (3)
4.	• STEMI with presumed successful treatment with fibrinolysis • Evidence of HF, recurrent ischemia, or unstable ventricular arrhythmias present • One-vessel CAD presumed to be the culprit artery	A (9)
5.	• STEMI with presumed successful treatment with fibrinolysis • Asymptomatic; no HF or no recurrent ischemic symptoms, or no unstable ventricular arrhythmias • Normal LVEF • One-vessel CAD presumed to be the culprit artery	U (5)
6.	• STEMI with presumed successful treatment with fibrinolysis • Asymptomatic; no HF, no recurrent ischemic symptoms, or no unstable ventricular arrhythmias at time of presentation • Depressed LVEF • Three-vessel CAD • Elective/semielective revascularization	A (8)
7.	• STEMI with successful treatment of the culprit artery by primary PCI or fibrinolysis • Asymptomatic; no HF, no evidence of recurrent or provokable ischemia, or no unstable ventricular arrhythmias during index hospitalization • Normal LVEF • Revascularization of a non-infarct-related artery during index hospitalization	I (2)
8.	• STEMI or NSTEMI and successful PCI of culprit artery during index hospitalization • Symptoms of recurrent myocardial ischemia and/or high-risk findings on noninvasive stress testing performed after index hospitalization • Revascularization of ≥1 additional coronary arteries	A (8)
9.	• UA/NSTEMI and low-risk features (e.g., TIMI score ≤2) for short-term risk of death or nonfatal MI • Revascularization of the presumed culprit artery	U (6)
10.	• UA/NSTEMI and intermediate-risk features (e.g., TIMI score 3–4) for short-term risk of death or nonfatal MI • Revascularization of the presumed culprit artery	A (8)
11.	• UA/NSTEMI and high-risk features for short-term risk of death or nonfatal MI • Revascularization of the presumed culprit artery	A (9)
12.	• UA/NSTEMI and high-risk features for short-term risk of death or nonfatal MI • Revascularization of multiple coronary arteries when the culprit artery cannot clearly be determined	A (9)
13.	• Patients with acute myocardial infarction (STEMI or NSTEMI) • Evidence of cardiogenic shock • Revascularization of ≥1 coronary arteries	A (8)

New and updated indications are shaded blue.

A = appropriate; CAD = coronary artery disease; HF = heart failure; I = inappropriate; LVEF = left ventricular ejection fraction; MI = myocardial infarction; NSTEMI = non–ST-segment elevation myocardial infarction; PCI = percutaneous coronary intervention; STEMI =ST-segment elevation myocardial infarction; TIMI = Thrombolysis In Myocardial Infarction; U = uncertain; UA = unstable angina.

Table 2. Patients Without Prior Bypass Surgery

Indication		Appropriate Use Score (1–9)		
	CCS Angina Class	Asymptomatic	I or II	III or IV
14.	• One- or 2-vessel CAD without involvement of proximal LAD • Low-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	I (1)	I (2)	U (5)
15.	• One- or 2-vessel CAD without involvement of proximal LAD • Low-risk findings on noninvasive testing • Receiving a course of maximal anti-ischemic medical therapy	I (2)	U (5)	A (7)
16.	• One- or 2-vessel CAD without involvement of proximal LAD • Intermediate-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	I (3)	U (5)	U (6)
17.	• One- or 2-vessel CAD without involvement of proximal LAD • Intermediate-risk findings on noninvasive testing • Receiving a course of maximal anti-ischemic medical therapy	U (4)	A (7)	A (8)
18.	• One- or 2-vessel CAD without involvement of proximal LAD • High-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	U (6)	A (7)	A (8)
19.	• One- or 2-vessel CAD without involvement of proximal LAD • High-risk findings on noninvasive testing • Receiving a course of maximal anti-ischemic medical therapy	A (7)	A (8)	A (9)
20.	• One- or 2-vessel CAD without involvement of proximal LAD • No noninvasive testing performed	I (3)	U (5)	A (7)
21.	• One- or 2-vessel CAD with borderline stenosis “50% to 60%” • No noninvasive testing performed • No further invasive evaluation performed (i.e., FFR, IVUS)	Not rated	I (2)	I (3)
22.	• One- or 2-vessel CAD with borderline stenosis “50% to 60%” • No noninvasive testing performed or equivocal test results present • FFR less than or equal to 0.80* and/or IVUS with significant reduction in cross-sectional area	I (3)	U (6)	A (7)
23.	• One- or 2-vessel CAD with borderline stenosis “50% to 60%” • No noninvasive testing performed or equivocal test results present • FFR or IVUS findings do not meet criteria for significant stenosis	I (1)	I (2)	I (2)
24.	• Chronic total occlusion of 1 major epicardial coronary artery, without other coronary stenoses • Low-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	I (1)	I (2)	I (3)
25.	• Chronic total occlusion of 1 major epicardial coronary artery, without other coronary stenoses • Low-risk findings on noninvasive testing • Receiving a course of maximal anti-ischemic medical therapy	I (1)	U (4)	U (6)
26.	• Chronic total occlusion of 1 major epicardial coronary artery, without other coronary stenoses • Intermediate-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	I (3)	U (4)	U (6)
27.	• Chronic total occlusion of 1 major epicardial coronary artery, without other coronary stenoses • Intermediate-risk criteria on noninvasive testing • Receiving a course of maximal anti-ischemic medical therapy	U (4)	U (5)	A (7)
28.	• Chronic total occlusion of 1 major epicardial coronary artery, without other coronary stenoses • High-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	U (4)	U (5)	A (7)
29.	• Chronic total occlusion of 1 major epicardial coronary artery, without other coronary stenoses • High-risk criteria on noninvasive testing • Receiving a course of maximal anti-ischemic medical therapy	U (5)	A (7)	A (8)
30.	• One-vessel CAD involving the proximal LAD • Low-risk findings on noninvasive testing • Receiving no or minimal anti-ischemic medical therapy	U (4)	U (5)	A (7)

Table 4. Method of Revascularization: Multivessel CAD, CCS Angina Greater Than or Equal to Class III, and/or Evidence of Intermediate- to High-Risk Findings on Noninvasive Testing*

Indication		Appropriate Use Score (1–9)	
		PCI	CABG
62.	• Two-vessel CAD with proximal LAD stenosis	A (7)	A (8)
63.	• Three-vessel CAD with low CAD burden (i.e., 3 focal stenoses, low SYNTAX score)	A (7)	A (9)
64.	• Three-vessel CAD with intermediate to high CAD burden (i.e., multiple diffuse lesions, presence of CTO, or high SYNTAX score)	U (4)	A (9)
65.	• Isolated left main stenosis	U (6)	A (9)
66.	• Left main stenosis and additional CAD with low CAD burden (i.e., 1- to 2-vessel additional involvement, low SYNTAX score)	U (5)	A (9)
67.	• Left main stenosis and additional CAD with intermediate to high CAD burden (i.e., 3-vessel involvement, presence of CTO, or high SYNTAX score)	I (3)	A (9)
68.	• Prior bypass surgery with native 3-vessel disease and failure of multiple bypass grafts • LIMA remains patent to a native coronary artery • Depressed LVEF	U (6)	A (7)
69.	• Prior bypass surgery with native 3-vessel disease and failure of multiple bypass grafts • LIMA was used as a graft but is no longer functional • Depressed LVEF	A (8)	U (6)

New and updated indications are shaded blue. *The 2009 appropriate use criteria (1) separated out diabetes and normal or depressed LVEF for the indications in this table, but they were combined for the focused update because these clinical variables did not affect the ratings.

A = appropriate; CABG = coronary artery bypass graft; CAD = coronary artery disease; CCS = Canadian Cardiovascular Society; CTO = chronic total occlusion; I = inappropriate; LAD = left anterior descending coronary artery; LIMA = left internal mammary artery; LVEF = left ventricular ejection fraction; PCI = percutaneous coronary intervention; SYNTAX = Synergy Between PCI With TAXUS and Cardiac Surgery; U = uncertain.

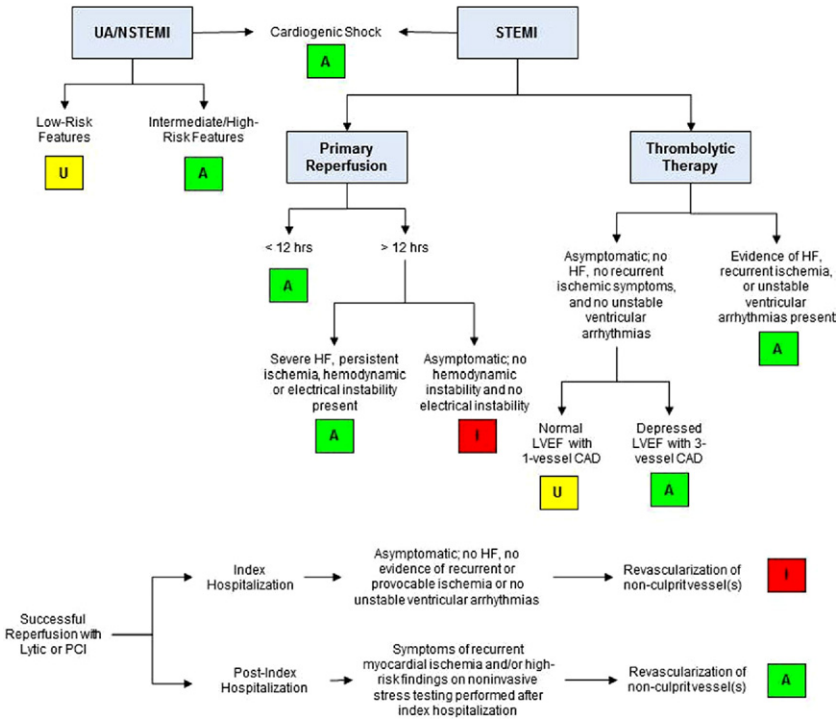

Figure 1. Appropriate Use Ratings for Revascularization in Acute Coronary Syndromes*

*The fact that the use of coronary revascularization for a particular condition is listed in this figure (appropriate, uncertain, inappropriate) does not preclude the use of other therapeutic modalities that may be equally effective. See the most current ACCF/AHA UA/NSTEMI and STEMI guidelines (16,23). A = appropriate; CAD = coronary artery disease; HF = heart failure; I = inappropriate; LVEF = left ventricular ejection fraction; PCI = percutaneous coronary intervention; STEMI = ST-elevation myocardial infarction; U = uncertain; UA/NSTEMI = unstable angina/non–ST-elevation myocardial infarction.

Rating Revascularization Methods

Mode of Revascularization (Indications 62 to 69)

Recognizing that variability in revascularization methods is often based upon patient factors and local practice patterns, the majority of indications are not intended to distinguish between the specific modes of revascularization (i.e., PCI vs. CABG). However, the writing group recognized that among patients with extensive or complex atherosclerosis, the mode of revascularization is also of interest when revascularization is deemed appropriate. Therefore, Table 4 presents clinical scenarios where the technical panelists were asked to consider the appropriate use of PCI and CABG as the revascularization method independently of each other (such that each modality would receive separate scores based on each specific clinical indication). These ratings are not intended to be a competitive ranking of PCI versus CABG, or to prioritize a specific approach when both are rated to have the same level of appropriateness.

Many of the known clinical factors that increase the risk of revascularization are shared between CABG and percutaneous methods. In the original AUC for revascularization, clinical scenarios were developed that included diabetes and LV function to stratify patients, but when rated, these features did not result in different ratings and thus were not used in this focused update. However, in an attempt to further stratify patients, the SYNTAX score is used in some of the new clinical scenarios.

The clinical scenarios below specifically apply to patients with multivessel CAD. It is assumed for these clinical scenarios that all patients have unacceptable levels of symptoms despite appropriate medical therapy and evidence of intermediate- to high-risk findings on noninvasive testing. In other words, the technical panel assumed that revascularization is appropriate and focused on rating the merit of the different modes with the intent of complete coronary revascularization for each indication.

In addition, it is assumed that no unusual extenuating circumstances exist (inability to comply with antiplatelet agents, patient is do not resuscitate status, patient preference strongly favoring 1 therapy or comorbidities likely to markedly increase procedural risk substantially). As such, the technical panel rated the appropriateness of PCI and CABG based on the information in the indication alone, assuming other variables are not present that would impact the decision.

Discussion

The ultimate objective of AUC is to improve patient care and health outcomes. The ACCF and its collaborators believe that careful blending of a broad range of clinical experiences and available evidence-based information will help guide a more efficient and equitable allocation of healthcare resources in cardiovascular revascularization. This approach is not intended to diminish the acknowledged difficulty or uncertainty of clinical decision making. Appropriate use criteria are not substitutes for sound clinical judgment and practice experience. It is acknowledged that some patients seen in clinical practice may not be represented in the AUC or have extenuating features when compared with the clinical scenarios presented.

Since the publication of the original coronary revascularization AUC, there has been substantial national focus on the variability and appropriateness of coronary revascularization. The 2009 AUC specifically for coronary revascularization by PCI has been mapped to the National Cardiovascular Data, Registry (NCDR) CathPCI registry data, and each institution's benchmarked results are now provided to member facilities in quarterly reports as a test quality metric. This initial assessment of PCI appropriateness within the NCDR data was also published by Chan and colleagues (19). Hospitals and operators are encouraged to review their specific reports as part of a quality improvement program to ensure data accuracy and increase the use of appropriate revascularization. Additionally, the SYNTAX trial, which was not formally published until 2009, was anticipated to possibly have an impact on the AUC. Despite calls for earlier updates of specific clinical scenarios, such as the isolated left main coronary artery revascularization, the writing group awaited the peer-reviewed publication of both the original trial data and the intermediate-term follow-up.

This focused update highlights 2 specific areas that were felt to require reconsideration: 1) specific indications that represent gaps identified when mapping the 2009 AUC to the CathPCI registry; and 2) re-evaluation of the indications for the treatment of multivessel CAD with symptoms by method (PCI and CABG) of revascularization as a result of data from the SYNTAX trial.

New Clinical Scenarios to Address Gaps

The 2009 AUC document only had 1 clinical scenario for UA/NSTEMI and high-risk features, which was graded as appropriate. The ratings for these new clinical scenarios (Indications 9 and 10) focus on patients with UA/NSTEMI and low- or intermediate-risk features as determined by the TIMI score. Revascularization in such patients with a low-risk score was graded as uncertain, meaning that revascularization may be reasonable, with the caveat that there is limited data on clinical benefit. For patients with an intermediate-risk score, revascularization was rated appropriate as it was for patients at high risk (Fig. 1).

In the 2009 AUC document, the clinical scenario of an asymptomatic patient without prior bypass surgery and with 1- or 2-vessel disease not involving the proximal LAD in whom no noninvasive testing had been performed was not evaluated because this clinical scenario was felt to be uncommon. However, for future mapping of the AUC to the CathPCI registry, the appropriateness of this clinical scenario was graded

Downloaded from content.onlinejacc.org by Peter Smith on February 11, 2012

in this focused update and determined to be inappropriate. This did not affect the appearance of Figures 2, 3, and 4 below because they include indications that were not updated.

PCI and CABG in Patients With Multivessel CAD

In this group of ratings, it is assumed that revascularization is appropriate, and the technical panel rated the appropriateness of the mode of revascularization independently for CABG and PCI (Fig. 5). The writing group and technical panel felt some quantification of CAD burden, either by description or SYNTAX score, could be helpful to clinicians. CABG was rated as appropriate in all of the new clinical scenarios developed, whereas PCI was rated as appropriate only in patients with 2-vessel CAD with involvement of the proximal LAD and in patients with 3-vessel disease with a low CAD burden. PCI for 3-vessel disease with a high CAD burden, however, was rated as uncertain. PCI for isolated left main stenosis is now graded as uncertain, as are scenarios with 3-vessel CAD with intermediate to high CAD burden and left main stenosis and additional CAD with low CAD burden. PCI is considered inappropriate for left main stenosis and additional CAD with intermediate to high CAD burden.

Clinical Judgment and Understanding the AUC Ratings

Although the appropriate use ratings reflect a general assessment of when revascularization may or may not be useful for specific patient populations, physicians and other stakeholders should continue to acknowledge the pivotal role of clinical judgment in determining whether revascularization is indicated for an individual patient. For example, the rating of a revascularization indication as inappropriate or uncertain should not preclude a provider from performing revascularization procedures when there are patient- and condition-specific data to support that decision. Indeed, this may reflect optimal clinical care, if supported by mitigating patient characteristics. Likewise, uncertain indications require individual physician judgment and understanding of the patient to better determine the usefulness of revascularization for a particular clinical scenario. The ranking of uncertain (4 to 6) **should not be viewed as excluding the use of revascularization for such patients**. Finally, there may be clinical scenarios in which the use of coronary revascularization for an indication considered to be appropriate does not always represent reasonable practice, such that the benefit of the procedure does not outweigh the risks. Accordingly, the AUC are intended to evaluate overall patterns of care regarding revascularization rather than adjudicating specific cases. In situations where there is substantial variation between the appropriate use rating and what the clinician believes is the best recommendation for the patient, further considerations or actions such as a second opinion may be appropriate. It is not anticipated that all physicians or facilities will have 100% of their revascularization procedures deemed appropriate. However, related to the overall patterns of care, if the national average of appropriate procedure ratings is 80%, e.g., and a physician or facility has only a 40% rate of appropriate procedures, further examination of the patterns of care may be warranted and helpful.

Stable Ischemic Heart Disease *With* Prior CABG

The writing group did not feel the focused update needed to address any clinical scenarios in patients with stable ischemic heart disease and prior CABG. These indications from the prior document show a pattern similar to that seen in patients without prior CABG; the presence of high-risk findings on noninvasive testing, higher severity of symptoms, or an increasing burden of disease in either the bypass grafts or native coronaries increased the likelihood of an appropriate rating. The only inappropriate ratings in patients with prior CABG were noted in patients receiving no or minimal anti-ischemic therapy or having low-risk findings on noninvasive testing. More uncertain ratings occurred in this group of patients, reflecting their higher complexity, higher risk, and the limited availability of published evidence regarding management outcome.

Application of Criteria

There are many potential applications for the AUC. Clinicians can use the ratings for decision support or as an educational tool when considering the need for revascularization. Moreover, these criteria can be used to facilitate discussion with patients and/or referring physicians about the need for revascularization. Facilities and payers may choose to use these criteria either prospectively in the design of protocols or pre-authorization procedures, or retrospectively for quality reports. It is hoped that payers would use these criteria to ensure that their members receive necessary, beneficial, and cost-effective cardiovascular care, rather than for other purposes.

It is expected that services performed for appropriate indications will receive reimbursement. In contrast, services performed for inappropriate indications may require additional documentation to justify payment because of the unique circumstances or the clinical profile that may exist in such a patient. This additional documentation should not be required for uncertain indications. It is critical to emphasize that the writing group, technical panel, AUC Task Force, and clinical community do not believe an uncertain rating justifies denial of reimbursement for revascularization. Rather, uncertain ratings are those in which the available data vary and many other factors exist that may affect the decision to perform or not perform revascularization. The opinions of the technical panel often varied for these indications, reflecting that additional research is needed. Indications with high clinical volume that are rated as uncertain identify important areas for further research. The AUC writing group and technical panel favor the collaborative interaction of cardiac surgeons and interventional cardiologists Heart Team approach regarding revascularization decisions in complex patients or coronary anatomy.

ARTICLE IN PRESS

When evaluating physician or facility performance, AUC should be used in conjunction with efforts that lead to quality improvement. Prospective pre-authorization procedures, if put in place, are most effective once a retrospective review has identified a pattern of potential inappropriate use. Because these criteria are based on current scientific evidence and the deliberations of the technical panel, they should be used prospectively to generate future discussions about reimbursement, but should not be applied retrospectively to cases completed before issuance of this report or documentation of centers/providers performing an unexpectedly high proportion of inappropriate cases as compared with their peers.

The writing group recognizes that these criteria will be evaluated during routine clinical care. To that end, specific data fields such as symptom status, presence or absence of acute coronary syndrome, history of bypass surgery, extent of ischemia on noninvasive imaging, CAD burden, and degree of antianginal therapy are anticipated to provide sufficient detail to determine individual appropriate use ratings. Because a reasonable and tolerated dose of antianginal therapy may vary significantly among different patients, the writing group continues to recommend the use of 2 classes of antianginal therapies as a minimum standard for medical therapy. The writing group also recognizes all data (e.g., visual assessment of stenosis severity, interpretation of noninvasive imaging, symptom severity) collected to assess appropriate use relies on its content accurately reflecting actual patient characteristics. Any current variability in these data points need to be addressed before accurate determination of appropriate use can be provided.

The primary objective of this report is to provide guidance regarding the suitability of coronary revascularization for diverse clinical scenarios. As with previous AUC documents, consensus among the technical panel members was desirable, but an attempt to achieve complete agreement within this diverse panel would have been artificial and was not the goal of the process. Two rounds of ratings with substantial discussion among the technical panel members between the ratings did lead to some consensus among panelists. However, further attempts to drive consensus would have diluted true differences in opinion among panelists and, therefore, was not undertaken. Moreover, remarkable concordance between the appropriateness ratings from the original criteria and 85 cardiologists not participating in the process, and blinded to the initial results, has been documented (20).

Future research analyzing patient outcomes for indications rated as appropriate will help ensure the equitable and efficient allocation of resources for coronary revascularization. Review of appropriateness patterns may also improve understanding of regional variations in the use of revascularization as highlighted in the Dartmouth Atlas Project (21). Further exploration of the indications rated as uncertain will help generate the information required to further define the appropriate use of coronary revascularization. Additionally, the criteria will need to be updated with the publication of ongoing trials in coronary revascularization and new clinical practice guidelines. For additional information and discussion of the literature, please see the ACCF/AHA PCI and CABG guidelines (12,13).

In conclusion, this document represents the current understanding of the clinical benefit of coronary revascularization with respect to health outcomes and survival. It is intended to provide a practical guide to clinicians and patients when considering revascularization. As with other AUC, the results of some of these ratings will require research and further evaluation to provide the greatest information and benefit to clinical decision making.

Appendix A: Additional Coronary Revascularization Definitions

Angina/Chest Pain Classification

Angina is a syndrome typically noted to include discomfort in the chest, jaw, shoulder, back, or arm that is aggravated by exertion or emotional stress and relieved by nitroglycerin. The quality of the discomfort, provoking factors, and relieving factors are used to define typical, atypical, and noncardiac chest pain. Atypical angina is generally defined by 2 of the above 3 characteristics, and noncardiac chest pain is generally defined as chest pain that meets 1 or none of the above criteria. These definitions are presented below.

Clinical Classification of Chest Pain (22):

- ***Typical* Angina (Definite):** Defined as 1) substernal chest pain or discomfort that is 2) provoked by exertion or emotional stress and 3) relieved by rest and/or nitroglycerin.
- ***Atypical* Angina (Probable):** Chest pain or discomfort that **lacks 1** of the characteristics of definite or typical angina.
- ***Nonanginal* Chest Pain:** Chest pain or discomfort that **meets 1 or none** of the typical angina characteristics.

The writing group assumes that noninvasive assessments of coronary anatomy (i.e., cardiac computed tomography, cardiac magnetic resonance angiography) provide anatomic information that is potentially similar to x-ray angiography. However, these modalities do not currently provide information on ischemic burden and are not assumed to be present in the clinical scenarios.

Invasive Methods of Determining Hemodynamic Significance

The writing group recognizes that not all patients referred for revascularization will have previous noninvasive testing. In fact, there are several situations in which patients may be appropriately referred for coronary angiography based on symptom presentation and a high pretest probability of coronary artery disease. In these settings, there may be

Table A2. Noninvasive Risk Stratification

High-risk (>3% annual mortality rate)
1. Severe resting left ventricular dysfunction (LVEF <35%)
2. High-risk treadmill score (score ≤−11)
3. Severe exercise left ventricular dysfunction (exercise LVEF <35%)
4. Stress-induced large perfusion defect (particularly if anterior)
5. Stress-induced multiple perfusion defects of moderate size
6. Large, fixed perfusion defect with LV dilation or increased lung uptake (thallium-201)
7. Stress-induced moderate perfusion defect with LV dilation or increased lung uptake (thallium-201)
8. Echocardiographic wall motion abnormality (involving >2 segments) developing at low dose of dobutamine (≤10 mg/kg/min) or at a low heart rate (<120 beats/min)
9. Stress echocardiographic evidence of extensive ischemia
Intermediate-risk (1% to 3% annual mortality rate)
1. Mild/moderate resting left ventricular dysfunction (LVEF 35% to 49%)
2. Intermediate-risk treadmill score (score between −11 and <5)
3. Stress-induced moderate perfusion defect without LV dilation or increased lung intake (thallium-201)
4. Limited stress echocardiographic ischemia with a wall motion abnormality only at higher doses of dobutamine involving less than or equal to 2 segments
Low-risk (<1% annual mortality rate)
1. Low-risk treadmill score (score ≥5)
2. Normal or small myocardial perfusion defect at rest or with stress*
3. Normal stress echocardiographic wall motion or no change of limited resting wall motion abnormalities during stress*

*Although the published data are limited, patients with these findings will probably not be at low risk in the presence of either a high-risk treadmill score or severe resting left ventricular dysfunction (LVEF <35%). Reprinted with permission from Patel et al. (1).
LV = left ventricular; LVEF = left ventricular ejection fraction.

situations where angiography shows a coronary narrowing of questionable hemodynamic importance in a patient with symptoms that can be related to myocardial ischemia. In such patients, the use of additional invasive measurements (such as fractional flow reserve or intravascular ultrasound) at the time of diagnostic angiography may be very helpful in further defining the need for revascularization and substituted for stress test findings (Table A2).

Appendix B: Additional Methods

See the earlier Methods section of the report for a description of technical panel selection, indication development, scope of indications, and rating process.

Relationships With Industry and Other Entities

The American College of Cardiology Foundation and its partnering organizations rigorously avoid any actual, perceived, or potential conflicts of interest that might arise as a result of an outside relationship or personal interest of a member of the technical panel. Specifically, all panelists are asked to provide disclosure statements of all relationships that might be perceived as real or potential conflicts of interest. These statements were reviewed by the AUC Task Force, discussed with all members of the technical panel at the face-to-face meeting, and updated and reviewed as necessary. A table of disclosures by all participants, who are listed in Appendix C, in the Appropriate Use Criteria for Coronary Revascularization can be found in Appendix D. In addition, to ensure complete transparency, complete disclosure information—including relationships not pertinent to this document—is available online as a document supplement.

Literature Review

The technical panel members were asked to refer to the relevant guidelines for a summary of the relevant literature, guideline recommendation tables, and reference lists provided for each indication table when completing their ratings (Online Appendix).

Appendix C: ACCF/SCAI/STS/AATS/AHA/ASNC/HFSA/SCCT 2012 Appropriate Use Criteria for Coronary Revascularization Focused Update Participants

Coronary Revascularization Writing Group

Manesh R. Patel, MD, FACC—Chair, Appropriate Use Criteria for Coronary Revascularization Writing Group—Assistant Professor of Medicine, Division of Cardiology, Assistant Director, Cardiac Catheterization Lab, Duke University Medical Center, Durham, NC

Gregory J. Dehmer, MD, FACC, FACP, FSCAI, FAHA—Past President, Society for Cardiovascular Angiography and Interventions; Professor of Medicine, Texas A&M School of Medicine; and Director, Cardiology Division, Scott & White Clinic, Temple, TX

John W. Hirshfeld, MD, FACC—Professor of Medicine, Hospital of The University of Pennsylvania, Department of Medicine, Cardiovascular Medicine Division, Philadelphia, PA

Peter K. Smith, MD, FACC—Professor and Chief, Thoracic Surgery, Duke University, Durham, NC

John A. Spertus, MD, MPH, FACC—Professor, UMKC School of Medicine, Director of CV Education and Outcomes Research, MidAmerica Heart Institute of St. Luke's Hospital, Kansas City, MO

Coronary Revascularization Technical Panel

Frederick A. Masoudi, MD, MSPH, FACC, FAHA—Moderator for the Technical Panel—Associate Professor of Medicine (Cardiology), University of Colorado Denver, Aurora, CO

Ralph G. Brindis, MD, MPH, FACC, FSCAI*—Methodology Liaison for the Technical Panel—Regional Senior Advisor for Cardiovascular Disease, Northern California Kaiser Permanente; Clinical Professor of Medicine, University of California at San Francisco; Chief Medical Officer and Chairman, NCDR Management Board, American College of Cardiology Foundation, Washington, DC

This table represents the relevant relationships with industry and other entities that were disclosed by participants at the time of participation. It does not necessarily reflect relationships at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of 5% or more of the voting stock or share of the business entity, or ownership of $10,000 or more of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review. Participation does not imply endorsement of this document. *Relationships were recorded at the time of review for the 2009 publication. Because the reviewers did not review the focused update, their information was not updated for this document. †Significant relationship.

Preamble

The medical profession should play a central role in evaluating the evidence related to drugs, devices, and procedures for the detection, management, and prevention of disease. When properly applied, expert analysis of available data on the benefits and risks of these therapies and procedures can improve the quality of care, optimize patient outcomes, and favorably affect costs by focusing resources on the most effective strategies. An organized and directed approach to a thorough review of evidence has resulted in the production of clinical practice guidelines that assist physicians in selecting the best management strategy for an individual patient. Moreover, clinical practice guidelines can provide a foundation for other applications, such as performance measures, appropriate use criteria, and both quality improvement and clinical decision support tools.

The American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA) have jointly produced guidelines in the area of cardiovascular disease since 1980. The ACCF/AHA Task Force on Practice Guidelines (Task Force), charged with developing, updating, and revising practice guidelines for cardiovascular diseases and procedures, directs and oversees this effort. Writing committees are charged with regularly reviewing and evaluating all available evidence to develop balanced, patient-centric recommendations for clinical practice.

Experts in the subject under consideration are selected by the ACCF and AHA to examine subject-specific data and write guidelines in partnership with representatives from other medical organizations and specialty groups. Writing committees are asked to perform a formal literature review; weigh the strength of evidence for or against particular tests, treatments, or procedures; and include estimates of expected outcomes where such data exist. Patient-specific modifiers, comorbidities, and issues of patient preference that may influence the choice of tests or therapies are considered. When available, information from studies on cost is considered, but data on efficacy and outcomes constitute the primary basis for the recommendations contained herein.

In analyzing the data and developing recommendations and supporting text, the writing committee uses evidence-based methodologies developed by the Task Force (1). The Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm. The Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect. The writing committee reviews and ranks evidence supporting each recommendation with the weight of evidence ranked as LOE A, B, or C according to specific definitions that are included in Table 1. Studies are identified as observational, retrospective, prospective, or randomized where appropriate. For certain conditions for which inadequate data are available, recommendations are based on expert consensus and clinical experience and are ranked as LOE C. When recommendations at LOE C are supported by historical clinical data, appropriate references (including clinical reviews) are cited if available. For issues for which sparse data are available, a survey of current

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Table 1. Applying Classification of Recommendations and Level of Evidence

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	SIZE OF TREATMENT EFFECT: CLASS I *Benefit >>> Risk* Procedure/Treatment **SHOULD** be performed/ administered	CLASS IIa *Benefit >> Risk* *Additional studies with focused objectives needed* **IT IS REASONABLE** to perform procedure/administer treatment	CLASS IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment **MAY BE CONSIDERED**	CLASS III *No Benefit* or CLASS III *Harm* Procedure/ Test / Treatment COR III: No benefit — Not Helpful / No Proven Benefit COR III: Harm — Excess Cost w/o Benefit or Harmful / Harmful to Patients
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown/unclear/uncertain or not well established	COR III: No Benefit: is not recommended; is not indicated; should not be performed/ administered/ other; is not useful/ beneficial/ effective COR III: Harm: potentially harmful; causes harm; associated with excess morbidity/mortality; should not be performed/ administered/ other
Comparative effectiveness phrases†	treatment/strategy A is recommended/indicated in preference to treatment B treatment A should be chosen over treatment B	treatment/strategy A is probably recommended/indicated in preference to treatment B it is reasonable to choose treatment A over treatment B		

A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

practice among the clinicians on the writing committee is the basis for LOE C recommendations, and no references are cited. The schema for COR and LOE is summarized in Table 1, which also provides suggested phrases for writing recommendations within each COR. A new addition to this methodology is separation of the Class III recommendations to delineate if the recommendation is determined to be of "no benefit" or is associated with "harm" to the patient. In addition, in view of the increasing number of comparative effectiveness studies, comparator verbs and suggested phrases for writing recommendations for the comparative effectiveness of one treatment or strategy versus another have been added for COR I and IIa, LOE A or B only.

In view of the advances in medical therapy across the spectrum of cardiovascular diseases, the Task Force has designated the term *guideline–directed medical therapy (GDMT)* to represent optimal medical therapy as defined by ACCF/AHA guideline–recommended therapies (primarily Class I). This new term, GDMT, will be used herein and throughout all future guidelines.

Because the ACCF/AHA practice guidelines address patient populations (and healthcare providers) residing in North America, drugs that are not currently available in North America are discussed in the text without a specific COR. For studies performed in large numbers of subjects outside North America, each writing committee reviews the

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

potential influence of different practice patterns and patient populations on the treatment effect and relevance to the ACCF/AHA target population to determine whether the findings should inform a specific recommendation.

The ACCF/AHA practice guidelines are intended to assist healthcare providers in clinical decision making by describing a range of generally acceptable approaches to the diagnosis, management, and prevention of specific diseases or conditions. The guidelines attempt to define practices that meet the needs of most patients in most circumstances. The ultimate judgment regarding the care of a particular patient must be made by the healthcare provider and patient in light of all the circumstances presented by that patient. As a result, situations may arise for which deviations from these guidelines may be appropriate. Clinical decision making should involve consideration of the quality and availability of expertise in the area where care is provided. When these guidelines are used as the basis for regulatory or payer decisions, the goal should be improvement in quality of care. The Task Force recognizes that situations arise in which additional data are needed to inform patient care more effectively; these areas will be identified within each respective guideline when appropriate.

Prescribed courses of treatment in accordance with these recommendations are effective only if followed. Because lack of patient understanding and adherence may adversely affect outcomes, physicians and other healthcare providers should make every effort to engage the patient's active participation in prescribed medical regimens and lifestyles. In addition, patients should be informed of the risks, benefits, and alternatives to a particular treatment and be involved in shared decision making whenever feasible, particularly for COR IIa and IIb, where the benefit-to-risk ratio may be lower.

The Task Force makes every effort to avoid actual, potential, or perceived conflicts of interest that may arise as a result of industry relationships or personal interests among the members of the writing committee. All writing committee members and peer reviewers of the guideline are required to disclose all such current relationships, as well as those existing 12 months previously. In December 2009, the ACCF and AHA implemented a new policy for relationships with industry and other entities (RWI) that requires the writing committee chair plus a minimum of 50% of the writing committee to have no relevant RWI (Appendix 1 for the ACCF/AHA definition of relevance). These statements are reviewed by the Task Force and all members during each conference call and meeting of the writing committee and are updated as changes occur. All guideline recommendations require a confidential vote by the writing committee and must be approved by a consensus of the voting members. Members are not permitted to write, and must recuse themselves from voting on, any recommendation or section to which their RWI apply. Members who recused themselves from voting are indicated in the list of writing committee members, and section recusals are noted in Appendix 1. Authors' and peer reviewers' RWI pertinent to this guideline are disclosed in Appendixes 1 and 2, respectively.

Additionally, to ensure complete transparency, writing committee members' comprehensive disclosure information—including RWI not pertinent to this document—is available as an online supplement. Comprehensive disclosure information for the Task Force is also available online at www.cardiosource.org/ACC/About-ACC/Leadership/Guidelines-and-Documents-Task-Forces.aspx. The work of the writing committee was supported exclusively by the ACCF and AHA without commercial support. Writing committee members volunteered their time for this activity.

In an effort to maintain relevance at the point of care for practicing physicians, the Task Force continues to oversee an ongoing process improvement initiative. As a result, in response to pilot projects, evidence tables (with references linked to abstracts in PubMed) have been added.

In April 2011, the Institute of Medicine released 2 reports: *Finding What Works in Health Care: Standards for Systematic Reviews* and *Clinical Practice Guidelines We Can Trust* (2,3). It is noteworthy that the ACCF/AHA guidelines are cited as being compliant with many of the proposed standards. A thorough review of these reports and of our current methodology is under way, with further enhancements anticipated.

The recommendations in this guideline are considered current until they are superseded by a focused update or the full-text guideline is revised. Guidelines are official policy of both the ACCF and AHA.

Alice K. Jacobs, MD, FACC, FAHA Chair
ACCF/AHA Task Force on Practice Guidelines

1. Introduction

1.1. Methodology and Evidence Review

Whenever possible, the recommendations listed in this document are evidence based. Articles reviewed in this guideline revision covered evidence from the past 10 years through January 2011, as well as selected other references through April 2011. Searches were limited to studies, reviews, and other evidence conducted in human subjects that were published in English. Key search words included but were not limited to the following: *analgesia*, *anastomotic techniques*, *antiplatelet agents*, *automated proximal clampless anastomosis device*, *asymptomatic ischemia*, *Cardica C-port*, *cost effectiveness*, *depressed left ventricular (LV) function*, *distal anastomotic techniques*, *direct proximal anastomosis on aorta*, *distal anastomotic devices*, *emergency coronary artery bypass graft (CABG) and ST-elevation myocardial infarction (STEMI)*, *heart failure*, *interrupted sutures*, *LV systolic dysfunction, magnetic connectors*, *PAS-Port automated proximal clampless anastomotic device*, *patency*, *proximal connectors*, *renal disease*, *sequential anastomosis*, *sternotomy*, *symmetry connector*, *symptomatic ischemia*, *proximal connectors*, *sequential anastomosis*, *T grafts*, *thoracotomy*, *U-clips*, *Ventrica Magnetic Vascular Port system*, *Y grafts*. Additionally, the committee reviewed documents related to the subject matter previously published by the

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

ACCF and AHA. References selected and published in this document are representative but not all-inclusive.

To provide clinicians with a comprehensive set of data, whenever deemed appropriate or when published, the absolute risk difference and number needed to treat or harm are provided in the guideline, along with confidence interval (CI) and data related to the relative treatment effects such as odds ratio (OR), relative risk (RR), hazard ratio (HR), or incidence rate ratio.

The focus of these guidelines is the safe, appropriate, and efficacious performance of CABG.

1.2. Organization of the Writing Committee

The committee was composed of acknowledged experts in CABG, interventional cardiology, general cardiology, and cardiovascular anesthesiology. The committee included representatives from the ACCF, AHA, American Association for Thoracic Surgery, Society of Cardiovascular Anesthesiologists, and Society of Thoracic Surgeons (STS).

1.3. Document Review and Approval

This document was reviewed by 2 official reviewers, each nominated by both the ACCF and the AHA, as well as 1 reviewer each from the American Association for Thoracic Surgery, Society of Cardiovascular Anesthesiologists, and STS, as well as members from the ACCF/AHA Task Force on Data Standards, ACCF/AHA Task Force on Performance Measures, ACCF Surgeons' Scientific Council, ACCF Interventional Scientific Council, and Southern Thoracic Surgical Association. All information on reviewers' RWI was distributed to the writing committee and is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACCF and the AHA and endorsed by the American Association for Thoracic Surgery, Society of Cardiovascular Anesthesiologists, and STS.

2. Procedural Considerations

2.1. Intraoperative Considerations

2.1.1. Anesthetic Considerations: Recommendations

CLASS I

1. Anesthetic management directed toward early postoperative extubation and accelerated recovery of low- to medium-risk patients undergoing uncomplicated CABG is recommended (4–6). *(Level of Evidence: B)*
2. Multidisciplinary efforts are indicated to ensure an optimal level of analgesia and patient comfort throughout the perioperative period (7–11). *(Level of Evidence: B)*
3. Efforts are recommended to improve interdisciplinary communication and patient safety in the perioperative environment (e.g., formalized checklist-guided multidisciplinary communication) (12–15). *(Level of Evidence: B)*
4. A fellowship-trained cardiac anesthesiologist (or experienced board-certified practitioner) credentialed in the use of perioperative transesophageal echocardiography (TEE) is recommended to provide or supervise anesthetic care of patients who are considered to be at high risk (16–18). *(Level of Evidence: C)*

CLASS IIa

1. Volatile anesthetic-based regimens can be useful in facilitating early extubation and reducing patient recall (5,19–21). *(Level of Evidence: A)*

CLASS IIb

1. The effectiveness of high thoracic epidural anesthesia/analgesia for routine analgesic use is uncertain (22–25). *(Level of Evidence: B)*

CLASS III: HARM

1. Cyclooxygenase-2 inhibitors are not recommended for pain relief in the postoperative period after CABG (26,27). *(Level of Evidence: B)*
2. Routine use of early extubation strategies in facilities with limited backup for airway emergencies or advanced respiratory support is potentially harmful. *(Level of Evidence: C)*

See Online Data Supplement 1 for additional data on anesthetic considerations.

Anesthetic management of the CABG patient mandates a favorable balance of myocardial oxygen supply and demand to prevent or minimize myocardial injury (Section 2.1.8). Historically, the popularity of several anesthetic techniques for CABG has varied on the basis of their known or potential adverse cardiovascular effects (e.g., cardiovascular depression with high doses of volatile anesthesia, lack of such depression with high-dose opioids, or coronary vasodilation and concern for a "steal" phenomenon with isoflurane) as well as concerns about interactions with preoperative medications (e.g., cardiovascular depression with beta blockers or hypotension with angiotensin-converting enzyme [ACE] inhibitors and angiotensin-receptor blockers [ARBs] [28–30]) (Sections 2.1.8 and 4.5). Independent of these concerns, efforts to improve outcomes and to reduce costs have led to shorter periods of postoperative mechanical ventilation and even, in some patients, to prompt extubation in the operating room ("accelerated recovery protocols" or "fast-track management") (5,31).

High-dose opioid anesthesia with benzodiazepine supplementation was used commonly in CABG patients in the United States in the 1970s and 1980s. Subsequently, it became clear that volatile anesthetics are protective in the setting of myocardial ischemia and reperfusion, and this, in combination with a shift to accelerated recovery or "fast-track" strategies, led to their ubiquitous use. As a result, opioids have been relegated to an adjuvant role (32,33). Despite their widespread use, volatile anesthetics have not been shown to provide a mortality rate advantage when compared with other intravenous regimens (Section 2.1.8).

Optimal anesthesia care in CABG patients should include 1) a careful preoperative evaluation and treatment of modifiable risk factors; 2) proper handling of all medications given preoperatively (Sections 4.1, 4.3, and 4.5); 3) establishment of central venous access and careful cardiovascular monitoring; 4) induction of a state of unconsciousness, analgesia, and immobility; and 5) a smooth transition to the

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

early postoperative period, with a goal of early extubation, patient mobilization, and hospital discharge. Attention should be directed at preventing or minimizing adverse hemodynamic and hormonal alterations that may induce myocardial ischemia or exert a deleterious effect on myocardial metabolism (as may occur during cardiopulmonary bypass [CPB]) (Section 2.1.8). This requires close interaction between the anesthesiologist and surgeon, particularly when manipulation of the heart or great vessels is likely to induce hemodynamic instability. During on-pump CABG, particular care is required during vascular cannulation and weaning from CPB; with off-pump CABG, the hemodynamic alterations often caused by displacement or verticalization of the heart and application of stabilizer devices on the epicardium, with resultant changes in heart rate, cardiac output, and systemic vascular resistance, should be monitored carefully and managed appropriately.

In the United States, nearly all patients undergoing CABG receive general anesthesia with endotracheal intubation utilizing volatile halogenated general anesthetics with opioid supplementation. Intravenous benzodiazepines often are given as premedication or for induction of anesthesia, along with other agents such as propofol or etomidate. Nondepolarizing neuromuscular-blocking agents, particularly nonvagolytic agents with intermediate duration of action, are preferred to the longer-acting agent, pancuronium. Use of the latter is associated with higher intraoperative heart rates and a higher incidence of residual neuromuscular depression in the early postoperative period, with a resultant delay in extubation (23,34). In addition, low concentrations of volatile anesthetic usually are administered via the venous oxygenator during CPB, facilitating amnesia and reducing systemic vascular resistance.

Outside the United States, alternative anesthetic techniques, particularly total intravenous anesthesia via propofol and opioid infusions with benzodiazepine supplementation with or without high thoracic epidural anesthesia, are commonly used. The use of high thoracic epidural anesthesia exerts salutary effects on the coronary circulation as well as myocardial and pulmonary function, attenuates the stress response, and provides prolonged postoperative analgesia (24,25,35). In the United States, however, concerns about the potential for neuraxial bleeding (particularly in the setting of heparinization, platelet inhibitors, and CPB-induced thrombocytopenia), local anesthetic toxicity, and logistical issues related to the timing of epidural catheter insertion and management have resulted in limited use of these techniques (22). Their selective use in patients with severe pulmonary dysfunction (Section 6.5) or chronic pain syndromes may be considered. Although meta-analyses of randomized controlled trials (RCTs) of high thoracic epidural anesthesia/analgesia in CABG patients (particularly on-pump) have yielded inconsistent results on morbidity and mortality rates, it does appear to reduce time to extubation, pain, and pulmonary complications (36–38). Of interest, although none of the RCTs have reported the occurrence of epidural hematoma or abscess, these entities occur on occasion (38). Finally, the use of other regional anesthetic approaches for postoperative analgesia, such as parasternal block, has been reported (39).

Over the past decade, early extubation strategies ("fast-track" anesthesia) often have been used in low- to medium-risk CABG patients. These strategies allow a shorter time to extubation, a decreased length of intensive care unit (ICU) stay, and variable effects on length of hospital stay (4–6). Immediate extubation in the operating room, with or without markedly accelerated postoperative recovery pathways (e.g., "ultra-fast-tracking," "rapid recovery protocol," "short-stay intensive care") have been used safely, with low rates of reintubation and no influence on quality of life (40–44). Observational data suggest that physician judgment in triaging lower-risk patients to early or immediate extubation works well, with rates of reintubation <1% (45). Certain factors appear to predict fast-track "failure," including previous cardiac surgery, use of intra-aortic balloon counterpulsation, and possibly advanced patient age.

Provision of adequate perioperative analgesia is important in enhancing patient mobilization, preventing pulmonary complications, and improving the patient's psychological well-being (9,11). The intraoperative use of high-dose morphine (40 mg) may offer superior postoperative pain relief and enhance patient well-being compared with fentanyl (despite similar times to extubation) (46).

The safety of nonsteroidal anti-inflammatory agents for analgesia is controversial, with greater evidence for adverse cardiovascular events with the selective cyclooxygenase-2 inhibitors than the nonselective agents. A 2007 AHA scientific statement presented a stepped-care approach to the management of musculoskeletal pain in patients with or at risk for coronary artery disease (CAD), with the goal of limiting the use of these agents to patients in whom safer therapies fail (47). In patients hospitalized with unstable angina (UA) and non–ST-elevation myocardial infarction (NSTEMI), these agents should be discontinued promptly and reinstituted later according to the stepped-care approach (48).

In the setting of cardiac surgery, nonsteroidal anti-inflammatory agents previously were used for perioperative analgesia. A meta-analysis of 20 trials of patients undergoing thoracic or cardiac surgery, which evaluated studies published before 2005, reported significant reductions in pain scores, with no increase in adverse outcomes (49). Subsequently, 2 RCTs, both studying the oral cyclooxygenase-2 inhibitor valdecoxib and its intravenous prodrug, parecoxib, reported a higher incidence of sternal infections in 1 trial and a significant increase in adverse cardiovascular events in the other (26,27). On the basis of the results of these 2 studies (as well as other nonsurgical reports of increased risk with cyclooxygenase-2–selective agents), the U.S. Food and Drug Administration in 2005 issued a "black box" warning for all nonsteroidal anti-inflammatory agents (except aspirin) immediately after CABG (50). The concurrent administration

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

of ibuprofen with aspirin has been shown to attenuate the latter's inhibition of platelet aggregation, likely because of competitive inhibition of cyclooxygenase at the platelet-receptor binding site (51).

Observational analyses in patients undergoing noncardiac surgery have shown a significant reduction in perioperative death with the use of checklists, multidisciplinary surgical care, intraoperative time-outs, postsurgical debriefings, and other communication strategies (14,15). Such methodology is being used increasingly in CABG patients (12–14).

In contrast to extensive literature on the role of the surgeon in determining outcomes with CABG, limited data on the influence of the anesthesiologist are available. Of 2 such reports from single centers in the 1980s, 1 suggested that the failure to control heart rate to ≤110 beats per minute was associated with a higher mortality rate, and the other suggested that increasing duration of CPB adversely influenced outcome (52,53). Another observational analysis of data from vascular surgery patients suggested that anesthetic specialization was independently associated with a reduction in mortality rate (54).

To meet the challenges of providing care for the increasingly higher-risk patients undergoing CABG, efforts have been directed at enhancing the experience of trainees, particularly in the use of newer technologies such as TEE. Cardiac anesthesiologists, in collaboration with cardiologists and surgeons, have implemented national training and certification processes for practitioners in the use of perioperative TEE (Section 2.1.7) (164,165). Accreditation of cardiothoracic anesthesia fellowship programs from the Accreditation Council for Graduate Medical Education was initiated in 2004, and efforts are ongoing to obtain formal subspecialty certification (18).

2.1.2. Use of CPB

Several adverse outcomes have been attributed to CPB, including 1) neurological deficits (e.g., stroke, coma, postoperative neurocognitive dysfunction); 2) renal dysfunction; and 3) the Systemic Inflammatory Response Syndrome (SIRS). The SIRS is manifested as generalized systemic inflammation occurring after a major morbid event, such as trauma, infection, or major surgery. It is often particularly apparent after on-pump cardiac surgery, during which surgical trauma, contact of blood with nonphysiological surfaces (e.g., pump tubing, oxygenator surfaces), myocardial ischemia and reperfusion, and hypothermia combine to cause a dramatic release of cytokines (e.g., interleukin [IL] 6 and IL8) and other mediators of inflammation (55). Some investigators have used serum concentrations of S100 beta as a marker of brain injury (56) and have correlated increased serum levels with the number of microemboli exiting the CPB circuit during CABG. In contrast, others have noted the increased incidence of microemboli with on-pump CABG (relative to off-pump CABG) but have failed to show a corresponding worsening of neurocognitive function 1 week to 6 months postoperatively (57,58). Blood retrieved from the operative field during on-pump CABG contains lipid material and particulate matter, which have been implicated as possible causes of postoperative neurocognitive dysfunction. Although a study (59) reported that CPB-associated neurocognitive dysfunction can be mitigated by the routine processing of shed blood with a cell saver before its reinfusion, another study (60) failed to show such an improvement.

It has been suggested that CPB leads to an increased incidence of postoperative renal failure requiring dialysis, but a large RCT comparing on-pump and off-pump CABG showed no difference in its occurrence (61). Of interest, this study failed to show a decreased incidence of postoperative adverse neurological events (stroke, coma, or neurocognitive deficit) in those undergoing off-pump CABG.

The occurrence of SIRS in patients undergoing CPB has led to the development of strategies designed to prevent or to minimize its occurrence. Many reports have focused on the increased serum concentrations of cytokines (e.g., IL-2R, IL-6, IL-8, tumor necrosis factor alpha) and other modulators of inflammation (e.g., P-selectin, sE-selectin, soluble intercellular adhesion molecule-1, plasma endothelial cell adhesion molecule-1, and plasma malondialdehyde), which reflect leukocyte and platelet activation, in triggering the onset of SIRS. A study showed a greater upregulation of neutrophil CD11b expression (a marker of leukocyte activation) in patients who sustained a ≥50% increase in the serum creatinine concentration after CPB, thereby implicating activated neutrophils in the pathophysiology of SIRS and the occurrence of post-CPB renal dysfunction (62). Modulating neutrophil activation to reduce the occurrence of SIRS has been investigated; however, the results have been inconsistent. Preoperative intravenous methylprednisolone (10 mg/kg) caused a reduction in the serum concentrations of many of these cytokines after CPB, but this reduction was not associated with improved hemodynamic variables, diminished blood loss, less use of inotropic agents, shorter duration of ventilation, or shorter ICU length of stay (63). Similarly, the use of intravenous immunoglobulin G in patients with post-CPB SIRS has not been associated with decreased rates of short-term morbidity or 28-day mortality (64).

Other strategies to mitigate the occurrence of SIRS after CPB have been evaluated, including the use of 1) CPB circuits (including oxygenators) coated with materials known to reduce complement and leukocyte activation; 2) CPB tubing that is covalently bonded to heparin; and 3) CPB tubing coated with polyethylene oxide polymer or Poly (2-methoxyethylacrylate). Leukocyte depletion via specialized filters in the CPB circuits has been shown to reduce the plasma concentrations of P-selectin, intercellular adhesion molecule-1, IL-8, plasma endothelial cell adhesion molecule-1, and plasma malondialdehyde after CPB (65).

Finally, closed mini-circuits for CPB have been developed in an attempt to minimize the blood–air interface and blood contact with nonbiological surfaces, both of which

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

promote cytokine elaboration, but it is uncertain if these maneuvers and techniques have a discernible effect on outcomes after CABG.

2.1.3. Off-Pump CABG Versus Traditional On-Pump CABG

Since the first CABG was performed in the late 1960s, the standard surgical approach has included the use of cardiac arrest coupled with CPB (so-called on-pump CABG), thereby optimizing the conditions for construction of vascular anastomoses to all diseased coronary arteries without cardiac motion or hemodynamic compromise. Such on-pump CABG has become the gold standard and is performed in about 80% of subjects undergoing the procedure in the United States. Despite the excellent results that have been achieved, the use of CPB and the associated manipulation of the ascending aorta are linked with certain perioperative complications, including myonecrosis during aortic occlusion, cerebrovascular accidents, generalized neurocognitive dysfunction, renal dysfunction, and SIRS. In an effort to avoid these complications, off-pump CABG was developed (58,66). Off-pump CABG is performed on the beating heart with the use of stabilizing devices (which minimize cardiac motion); in addition, it incorporates techniques to minimize myocardial ischemia and systemic hemodynamic compromise. As a result, the need for CPB is obviated. This technique does not necessarily decrease the need for manipulation of the ascending aorta during construction of the proximal anastomoses.

To date, the results of several RCTs comparing on-pump and off-pump CABG in various patient populations have been published (61,67,68). In addition, registry data and the results of meta-analyses have been used to assess the relative efficacies of the 2 techniques (69,70). In 2005, an AHA scientific statement comparing the 2 techniques concluded that both procedures usually result in excellent outcomes and that neither technique should be considered superior to the other (71). At the same time, several differences were noted. Off-pump CABG was associated with less bleeding, less renal dysfunction, a shorter length of hospital stay, and less neurocognitive dysfunction. The incidence of perioperative stroke was similar with the 2 techniques. On-pump CABG was noted to be less technically complex and allowed better access to diseased coronary arteries in certain anatomic locations (e.g., those on the lateral LV wall) as well as better long-term graft patency.

In 2009, the results of the largest RCT to date comparing on-pump CABG to off-pump CABG, the ROOBY (Randomized On/Off Bypass) trial, were published, reporting the outcomes for 2,203 patients (99% men) at 18 Veterans Affairs Medical Centers (61). The primary short-term endpoint, a composite of death or complications (reoperation, new mechanical support, cardiac arrest, coma, stroke, or renal failure) within 30 days of surgery, occurred with similar frequency (5.6% for on-pump CABG; 7.0% for off-pump CABG; $p=0.19$). The primary long-term endpoint, a composite of death from any cause, a repeat revascularization procedure, or a nonfatal myocardial infarction (MI) within 1 year of surgery, occurred more often in those undergoing off-pump CABG (9.9%) than in those having on-pump CABG (7.4%; $p=0.04$). Neuropsychological outcomes and resource utilization were similar between the 2 groups. One year after surgery, graft patency was higher in the on-pump group (87.8% versus 82.6%; $p<0.01$). In short, the ROOBY investigators failed to show an advantage of off-pump CABG compared with on-pump CABG in a patient population considered to be at low risk. Instead, use of the on-pump technique was associated with better 1-year composite outcomes and 1-year graft patency rates, with no difference in neuropsychological outcomes or resource utilization.

Although numerous investigators have used single-center registries, the STS database, and meta-analyses in an attempt to identify patient subgroups in whom off-pump CABG is the preferred procedure, even these analyses have reached inconsistent conclusions about off-pump CABG's ability to reduce morbidity and mortality rates (69,72–83). A retrospective cohort study of 14,766 consecutive patients undergoing isolated CABG identified a mortality benefit (OR: 0.45) for off-pump CABG in patients with a predicted risk of mortality >2.5% (82), but a subsequent randomized comparison of off-pump CABG to traditional on-pump CABG in 341 high-risk patients (a Euroscore >5) showed no difference in the composite endpoint of all-cause death, acute MI, stroke, or a required reintervention procedure (78). An analysis of data from the New York State Cardiac Surgery Reporting system did not demonstrate a reduction in mortality rate with off-pump CABG in any patient subgroup, including the elderly (age >80 years) or those with cerebrovascular disease, azotemia, or an extensively calcified ascending aorta (69).

Despite these results, off-pump CABG is the preferred approach by some surgeons who have extensive experience with it and therefore are comfortable with its technical nuances. Recently, published data suggested that the avoidance of aortic manipulation is the most important factor in reducing the risk of neurological complications (84,85). Patients with extensive disease of the ascending aorta pose a special challenge for on-pump CABG; for these patients, cannulation or cross-clamping of the aorta may create an unacceptably high risk of stroke. In such individuals, off-pump CABG in conjunction with avoidance of manipulation of the ascending aorta (including placement of proximal anastomoses) may be beneficial. Surgeons typically prefer an on-pump strategy in patients with hemodynamic compromise because CPB offers support for the systemic circulation. In the end, most surgeons consider either approach to be reasonable for the majority of subjects undergoing CABG.

ARTICLE IN PRESS

2.1.4. Bypass Graft Conduit: Recommendations

CLASS I

1. If possible, the left internal mammary artery (LIMA) should be used to bypass the left anterior descending (LAD) artery when bypass of the LAD artery is indicated (86–89). *(Level of Evidence: B)*

CLASS IIa

1. The right internal mammary artery (IMA) is probably indicated to bypass the LAD artery when the LIMA is unavailable or unsuitable as a bypass conduit. *(Level of Evidence: C)*
2. When anatomically and clinically suitable, use of a second IMA to graft the left circumflex or right coronary artery (when critically stenosed and perfusing LV myocardium) is reasonable to improve the likelihood of survival and to decrease reintervention (90–94). *(Level of Evidence: B)*

CLASS IIb

1. Complete arterial revascularization may be reasonable in patients less than or equal to 60 years of age with few or no comorbidities. *(Level of Evidence: C)*
2. Arterial grafting of the right coronary artery may be reasonable when a critical (≥90%) stenosis is present (89,93,95). *(Level of Evidence: B)*
3. Use of a radial artery graft may be reasonable when grafting left-sided coronary arteries with severe stenoses (>70%) and right-sided arteries with critical stenoses (≥90%) that perfuse LV myocardium (96–101). *(Level of Evidence: B)*

CLASS III: HARM

1. An arterial graft should not be used to bypass the right coronary artery with less than a critical stenosis (<90%) (89). *(Level of Evidence: C)*

Arteries (internal mammary, radial, gastroepiploic, and inferior epigastric) or veins (greater and lesser saphenous) may be used as conduits for CABG. The effectiveness of CABG in relieving symptoms and prolonging life is directly related to graft patency. Because arterial and venous grafts have different patency rates and modes of failure, conduit selection is important in determining the long-term efficacy of CABG.

2.1.4.1. SAPHENOUS VEIN GRAFTS

Reversed saphenous vein grafts (SVGs) are commonly used in patients undergoing CABG. Their disadvantage is a declining patency with time: 10% to as many as 25% of them occlude within 1 year of CABG (89,102,103); an additional 1% to 2% occlude each year during the 1 to 5 years after surgery; and 4% to 5% occlude each year between 6 and 10 years postoperatively (104). Therefore, 10 years after CABG, 50% to 60% of SVGs are patent, only half of which have no angiographic evidence of atherosclerosis (104). During SVG harvesting and initial exposure to arterial pressure, the endothelium often is damaged, which, if extensive, may lead to platelet aggregation and graft thrombosis. Platelet adherence to the endothelium begins the process of intimal hyperplasia that later causes SVG atherosclerosis (103,105). After adhering to the intima, the platelets release mitogens that stimulate smooth muscle cell migration, leading to intimal proliferation and hyperplasia. Lipid is incorporated into these areas of intimal hyperplasia, resulting in atherosclerotic plaque formation (106). The perioperative administration of aspirin and dipyridamole improves early (<1 month) and 1-year SVG patency and decreases lipid accumulation in the SVG intima (103, 106,107).

2.1.4.2. INTERNAL MAMMARY ARTERIES

Unlike SVGs, IMAs usually are patent for many years postoperatively (10-year patency >90%) (89,95,102,108–117) because of the fact that <4% of IMAs develop atherosclerosis, and only 1% have atherosclerotic stenoses of hemodynamic significance (118–120). This resistance to the development of atherosclerosis is presumably due to 1) the nearly continuous internal elastic lamina that prevents smooth muscle cell migration and 2) the release of prostacyclin and nitric oxide, potent vasodilators and inhibitors of platelet function, by the endothelium of IMAs (119,121,122).

The disadvantage of using the IMA is that it may spasm and eventually atrophy if used to bypass a coronary artery without a flow-limiting stenosis (89,95,118,123–130). Observational studies suggest an improved survival rate in patients undergoing CABG when the LIMA (rather than an SVG) is used to graft the LAD artery (86–88); this survival benefit is independent of the patient's sex, age, extent of CAD, and LV systolic function (87,88). Apart from improving survival rate, LIMA grafting of the LAD artery reduces the incidence of late MI, hospitalization for cardiac events, need for reoperation, and recurrence of angina (86,88). The LIMA should be used to bypass the LAD artery provided that a contraindication to its use (e.g., emergency surgery, poor LIMA blood flow, subclavian artery stenosis, radiation injury, atherosclerosis) is not present.

Because of the beneficial influence on morbidity and mortality rates of using the IMA for grafting, several centers have advocated bilateral IMA grafting in hopes of further improving CABG results (90,91,94). In fact, numerous observational studies have demonstrated improved morbidity and mortality rates when both IMAs are used. On the other hand, bilateral IMA grafting appears to be associated with an increased incidence of sternal wound infections in patients with diabetes mellitus and those who are obese (body mass index >30 kg/m^2).

2.1.4.3. RADIAL, GASTROEPIPLOIC, AND INFERIOR EPIGASTRIC ARTERIES

Ever since the observation that IMAs are superior to SVGs in decreasing the occurrence of ischemic events and prolonging survival, other arterial conduits, such as the radial, gastroepiploic, and inferior epigastric arteries, have been used in an attempt to improve the results of CABG. Information about these other arterial conduits is sparse in comparison to what is known about IMAs and SVGs, however. The radial artery is a muscular artery that is susceptible to spasm and atrophy when used to graft a coronary artery that is not severely narrowed. Radial artery

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

graft patency is best when used to graft a left-sided coronary artery with >70% stenosis and worst when it is used to bypass the right coronary artery with a stenosis of only moderate severity (96–100).

The gastroepiploic artery is most often used to bypass the right coronary artery or its branches, although it may be used to bypass the LAD artery if the length of the gastroepiploic artery is adequate. Similar to the radial artery, it is prone to spasm and therefore should only be used to bypass coronary arteries that are severely stenotic (131). The 1-, 5-, and 10-year patency rates of the gastroepiploic artery are reportedly 91%, 80%, and 62%, respectively (132).

The inferior epigastric artery is only 8 to 10 centimeters in length and therefore is usually used as a "Y" or "T" graft connected to another arterial conduit. On occasion it is used as a free graft from the aorta to a high diagonal branch of the LAD artery. Because it is a muscular artery, it is prone to spasm and therefore is best used to bypass a severely stenotic coronary artery. Its reported 1-year patency is about 90% (133,134).

2.1.5. Incisions for Cardiac Access

Although the time-honored incision for CABG is a median sternotomy, surgeons have begun to access the heart via several other approaches in an attempt to 1) reduce the traumatic effects often seen with full median sternotomy, 2) hasten postoperative recovery, and 3) enhance cosmesis. The utility and benefit of these smaller incisions has been evident in subjects undergoing valvular surgery, for which only limited access to the heart is required.

The most minimally invasive access incisions for CABG are seen with robotically assisted totally endoscopic CABG. A study showed that totally endoscopic CABG with robotic technology was associated with improved physical health, shorter hospital stay, and a more rapid return to the activities of daily living compared with traditional techniques. At present, direct comparisons of robotically assisted and conventional CABG are lacking (135).

The use of minimally invasive cardiac access incisions for CABG is limited. The need for adequate exposure of the ascending aorta and all surfaces of the heart to accomplish full revascularization usually precludes the use of minimal access incisions, such as upper sternotomy, lower sternotomy, or anterolateral thoracotomy. Nevertheless, use of limited incisions may increase in the future with the advent of hybrid strategies that use a direct surgical approach (usually for grafting the LAD artery through a small parasternal incision) and percutaneous coronary intervention (PCI) of the other diseased coronary arteries. The benefit of hybrid revascularization and hybrid operating rooms, in which PCI and CABG can be accomplished in one procedure, is yet to be determined. In patients with certain comorbid conditions, such as severe aortic calcification, previous chest irradiation, and obesity in combination with severe diabetes mellitus, full median sternotomy may be problematic (136), and hybrid revascularization may be preferable.

2.1.6. Anastomotic Techniques

At present, most coronary bypass grafts are constructed with hand-sewn suture techniques for the proximal and distal anastomoses, a practice that has resulted in good short- and intermediate-term patency rates. Because surgeons have different preferences with regard to the technical aspects of the procedure, a wide variety of suture configurations is used. Sewing of the proximal and distal anastomoses with a continuous polypropylene suture is commonly done, but techniques with interrupted silk sutures have been used, with similar results for graft patency and adverse events.

Certain clinical scenarios have precipitated an interest in alternative techniques of constructing coronary bypass anastomoses. Some surgeons and patients wish to avoid the potential morbidity and cosmetic results of a median sternotomy, yet the least invasive incisions usually are too small to allow hand-sewn anastomoses. To solve this problem, coronary connector devices have been developed for use with arterial or venous conduits to enable grafting without direct suturing. In addition, these devices have been used in subjects with diseased ascending aortas, in whom a technique that allows construction of a proximal anastomosis with minimal manipulation of the ascending aorta (typically by eliminating the need for aortic cross-clamping) may result in less embolization of debris, thereby reducing the occurrence of adverse neurological outcomes. In this situation, the operation is performed through a median sternotomy, and the proximal anastomoses are created with a connector (or may be hand-sewn with the assistance of a device that provides a bloodless operative field) without partial or complete clamping of the ascending aorta.

2.1.7. Intraoperative TEE: Recommendations

CLASS I

1. Intraoperative TEE should be performed for evaluation of acute, persistent, and life-threatening hemodynamic disturbances that have not responded to treatment (137,138). *(Level of Evidence: B)*
2. Intraoperative TEE should be performed in patients undergoing concomitant valvular surgery (137,139). *(Level of Evidence: B)*

CLASS IIa

1. Intraoperative TEE is reasonable for monitoring of hemodynamic status, ventricular function, regional wall motion, and valvular function in patients undergoing CABG (138,140–145). *(Level of Evidence: B)*

The use of intraoperative TEE in patients undergoing cardiac surgery has increased steadily since its introduction in the late 1980s. Although its utility is considered to be highest in patients undergoing valvular and complex open great-vessel/aortic surgery, it is commonly used in subjects undergoing CABG. TEE is most often used (146), although epicardial and epiaortic imaging, performed under aseptic conditions, allows visualization of imaging planes not possible with TEE (147,148). Specifically, epiaortic

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

imaging allows visualization of the "blind spot" of the ascending aorta (caused by interposition of the trachea with the esophagus), the site of aortic cannulation for CPB, from which dislodgement of friable atheroma, a major risk factor for perioperative stroke, may occur (Section 5.2.1). In addition, epicardial probes allow imaging when TEE is contraindicated, cannot be performed, or produces inadequate images. It can facilitate the identification of intraventricular thrombi when TEE images are equivocal.

The "2003 ACC/AHA/ASE Guideline Update for the Clinical Application of Echocardiography" based its recommendations on those reported in the 1996 American Society of Anesthesiologists/Society of Cardiovascular Anesthesiologists practice guideline and considered the use of TEE in CABG patients (149). The latter document was updated in 2010 (139). Because of the use of different grading methodologies in the American Society of Anesthesiologists/Society of Cardiovascular Anesthesiologists guideline relative to that of the ACCF/AHA, precise comparisons are difficult. However, it is noted that TEE "should be considered" in subjects undergoing CABG, to confirm and refine the preoperative diagnosis, detect new or unsuspected pathology, adjust the anesthetic and surgical plan accordingly, and assess the results of surgery. The strongest recommendation is given for treatment of acute life-threatening hemodynamic instability that has not responded to conventional therapies.

Observational cohort analyses and case reports have suggested the utility of TEE for diagnosing acute life-threatening hemodynamic or surgical problems in CABG patients, many of which are difficult or impossible to detect or treat without direct imaging. Evaluation of ventricular cross-sectional areas and ejection fraction (EF) and estimation or direct measurement of cardiac output by TEE may facilitate anesthetic, fluid, and inotropic/pressor management. The utility of echocardiography for the evaluation of LV end-diastolic area/volume and its potential superiority over pulmonary artery occlusion or pulmonary artery diastolic pressure, particularly in the early postoperative period, has been reported (150,151) (Section 4.10). In subjects without preoperative transthoracic imaging, intraoperative TEE may provide useful diagnostic information (over and above that detected during cardiac catheterization) on valvular function as well as evidence of pulmonary hypertension, intracardiac shunts, or other complications that may alter the planned surgery.

In patients undergoing CABG, intraoperative TEE is used most often for the detection of regional wall motion abnormalities (possibly caused by myocardial ischemia or infarction) and their effect on LV function. Observational studies have suggested that regional wall motion abnormalities detected with TEE can guide surgical therapy, leading to revision of a failed or inadequate conduit or the placement of additional grafts not originally planned. The presence of new wall motion abnormalities after CPB correlates with adverse perioperative and long-term outcomes (143).

Although the initial hope that an estimation of coronary blood flow with intramyocardial contrast enhancement visualized by TEE would facilitate surgical intervention has not been realized, technical advances in imaging of coronary arteries and grafts may ultimately provide reliable information. At present, the evaluation of graft flow with conventional nonimaging handheld Doppler probes appears adequate (Section 8). Intraoperative evaluation of mitral regurgitation may facilitate detection of myocardial ischemia and provide guidance about the need for mitral valve annuloplasty (Section 6.7). Newer technologies, including nonimaging methods for analyzing systolic and diastolic velocity and direction and timing of regional wall motion (Doppler tissue imaging and speckle tracking), as well as "real-time" 3-dimensional imaging, may facilitate the diagnosis of myocardial ischemia and evaluation of ventricular function. At present, however, their cost-effectiveness has not been determined, and they are too complex for routine use (152–154).

Among different centers, the rate of intraoperative TEE use in CABG patients varies from none to routine; its use is influenced by many factors, such as institutional and practitioner preferences, the healthcare system and reimbursement strategies, tertiary care status, and presence of training programs (155). The efficacy of intraoperative TEE is likely influenced by the presence of 1) LV systolic and diastolic dysfunction, 2) concomitant valvular disease, 3) the planned surgical procedure (on pump versus off pump, primary versus reoperative), 4) the surgical approach (full sternotomy versus partial sternotomy versus endoscopic or robotic), 5) its acuity (elective versus emergency); and 6) physician training and experience (137,138,140–142,144,145,156–163).

The safety of intraoperative TEE in patients undergoing cardiac surgery is uncertain. Retrospective analyses of data from patients undergoing diagnostic upper gastrointestinal endoscopy, nonoperative diagnostic TEE imaging, and intraoperative imaging by skilled operators in high-volume centers demonstrate a low frequency of complications related to insertion or manipulation of the probe (164,165). Nevertheless, minor (primarily pharyngeal injury from probe insertion) and major (esophageal perforation, gastric bleeding, or late mediastinitis) complications are reported (166,167). A more indolent complication is that of acquired dysphagia and possible aspiration postoperatively. Although retrospective analyses of postoperative cardiac surgical patients with clinically manifest esophageal dysfunction have identified TEE use as a risk factor (168–170), such dysfunction also has been reported in subjects in whom TEE was not used (171). Advanced age, prolonged intubation, and neurological injury seem to be risk factors for its development. The significance of the incidental intraoperative detection and repair of a patent foramen ovale, a common occurrence, is controversial (172). A 2009 obser-

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

vational analysis of 13,092 patients (25% isolated CABG; 29% CABG or other cardiac procedure), of whom 17% had a patent foramen ovale detected by TEE (28% of which were repaired), reported an increase in postoperative stroke in the patients who had patent foramen ovale repair (OR: 2.47; 95% CI: 1.02 to 6.0) with no improvement in long-term outcome (173).

2.1.8. Preconditioning/Management of Myocardial Ischemia: Recommendations

CLASS I

1. Management targeted at optimizing the determinants of coronary arterial perfusion (e.g., heart rate, diastolic or mean arterial pressure, and right ventricular or LV end-diastolic pressure) is recommended to reduce the risk of perioperative myocardial ischemia and infarction (53,174–177). *(Level of Evidence: B)*

CLASS IIa

1. Volatile-based anesthesia can be useful in reducing the risk of perioperative myocardial ischemia and infarction (178–181). *(Level of Evidence: A)*

CLASS IIb

1. The effectiveness of prophylactic pharmacological therapies or controlled reperfusion strategies aimed at inducing preconditioning or attenuating the adverse consequences of myocardial reperfusion injury or surgically induced systemic inflammation is uncertain (182–189). *(Level of Evidence: A)*
2. Mechanical preconditioning might be considered to reduce the risk of perioperative myocardial ischemia and infarction in patients undergoing off-pump CABG (190–192). *(Level of Evidence: B)*
3. Remote ischemic preconditioning strategies using peripheral-extremity occlusion/reperfusion might be considered to attenuate the adverse consequences of myocardial reperfusion injury (193–195). *(Level of Evidence: B)*
4. The effectiveness of postconditioning strategies to attenuate the adverse consequences of myocardial reperfusion injury is uncertain (196,197). *(Level of Evidence: C)*

See Online Data Supplements 2 to 4 for additional data on preconditioning.

Perioperative myocardial injury is associated with adverse outcomes after CABG (198–200), and available data suggest a direct correlation between the amount of myonecrosis and the likelihood of an adverse outcome (198,201–204) (Section 5.2.4).

The etiologies of perioperative myocardial ischemia and infarction and their complications (electrical or mechanical) range from alterations in the determinants of global or regional myocardial oxygen supply and demand to complex biochemical and microanatomic, systemic, or vascular abnormalities, many of which are not amenable to routine diagnostic and therapeutic interventions. Adequate surgical reperfusion is important in determining outcome, even though it may initially induce reperfusion injury. Various studies delineating the major mediators of reperfusion injury have focused attention on the mitochondrial permeability transition pore, the opening of which during reperfusion uncouples oxidative phosphorylation, ultimately leading to cell death (205). Although several pharmacological interventions targeting components of reperfusion injury have been tried, none has been found to be efficacious for this purpose (182,184–189,205–207).

The severity of reperfusion injury is influenced by numerous factors, including 1) the status of the patient's coronary circulation, 2) the presence of active ongoing ischemia or infarction, 3) preexisting medical therapy (Sections 4.3 and 4.5), 4) concurrent use of mechanical assistance to improve coronary perfusion (i.e., intra-aortic balloon counterpulsation), and 5) the surgical approach used (on pump or off pump). CPB with ischemic arrest is known to induce the release of cytokines and chemokines involved in cellular homeostasis, thrombosis, and coagulation; oxidative stress; adhesion of blood cell elements to the endothelium; and neuroendocrine stress responses; all of these may contribute to myocardial injury (208,209). Controlled reperfusion strategies during CPB, involving prolonged reperfusion with warm-blood cardioplegia in conjunction with metabolic enhancers, are rarely used in lieu of more routine methods of preservation (e.g., asystolic arrest, anterograde or retrograde blood cardioplegia during aortic cross-clamping). Several studies suggest that the magnitude of SIRS is greater with on-pump CABG than with off-pump CABG (201,208,210–213).

Initial studies of preconditioning used mechanical occlusion of arterial inflow followed by reperfusion via aortic cross-clamping immediately on institution of bypass or with coronary artery occlusion proximal to the planned distal anastomosis during off-pump CABG (190,191,214–217). Because of concerns of the potential adverse cerebral effects of aortic manipulation, enthusiasm for further study of this technique in on-pump CABG patients is limited (Section 5.2.1). Despite intense interest in the physiology of post-conditioning, few data are available (197). A small 2008 study in patients undergoing valve surgery, which used repeated manipulation of the ascending aorta, reported a reduction in surrogate markers of inflammation and myonecrosis (196). In lieu of techniques utilizing mechanical occlusion, pharmacological conditioning agents are likely to be used. An alternative approach that avoids much (but not all) of the safety concerns related to potential vascular injury is remote preconditioning of arterial inflow to the leg or (more commonly) the arm via blood pressure cuff occlusion (218). Two studies of patients undergoing on-pump CABG at a single center, the first of which used 2 different myocardial protection strategies and the second of which repeated the study with a standardized cold-blood cardioplegia routine, reported similar amounts of troponin release during the 72 hours postoperatively, with no apparent complications (193,195). A larger trial was unable to confirm any benefits of a similar protocol, casting doubt on the utility of this approach (194).

Volatile halogenated anesthetics and opioids have antiischemic or conditioning properties (32,33,219,220), and propofol has antioxidant properties of potential value in

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

subjects with reperfusion injury (221,222). The salutary properties of volatile anesthetics during myocardial ischemia are well known. Their negative inotropic and chronotropic effects are considered to be beneficial, particularly in the setting of elevated adrenergic tone that is common with surgical stimulation. Although contemporary volatile agents demonstrate some degree of coronary arterial vasodilation (with isoflurane considered the most potent), the role of a "steal phenomena" in the genesis of ischemia is considered to be trivial (33). In comparison to propofol/opioid infusions, volatile agents seem to reduce troponin release, preserve myocardial function, and improve resource utilization (i.e., ICU or hospital lengths of stay) and 1-year outcome (223–227). It is postulated that multiple factors that influence myocardial preservation modulate the potential impact of a specific anesthetic regimen.

Observational analyses have reported an association between elevated perioperative heart rates and adverse outcomes (228,229), but it is difficult to recommend a specific heart rate for all CABG patients. Instead, the heart rate may need to be adjusted up or down to maintain an adequate cardiac output (230,231). Similarly, controversy exists about management of blood pressure in the perioperative period (232), particularly with regard to systolic pressure (233) and pulse pressure (234). Intraoperative hypotension is considered to be a risk factor for adverse outcomes in patients undergoing many types of surgery. Unique to CABG are unavoidable periods of hypotension associated with surgical manipulation, cannulation for CPB, weaning from CPB, or during suspension and stabilization of the heart with off-pump CABG. Minimization of such periods is desirable but is often difficult to achieve, particularly in patients who are unstable hemodynamically.

2.2. Clinical Subsets

2.2.1. CABG in Patients With Acute MI: Recommendations

CLASS I

1. Emergency CABG is recommended in patients with acute MI in whom 1) primary PCI has failed or cannot be performed, 2) coronary anatomy is suitable for CABG, and 3) persistent ischemia of a significant area of myocardium at rest and/or hemodynamic instability refractory to nonsurgical therapy is present (235–239). *(Level of Evidence: B)*
2. Emergency CABG is recommended in patients undergoing surgical repair of a postinfarction mechanical complication of MI, such as ventricular septal rupture, mitral valve insufficiency because of papillary muscle infarction and/or rupture, or free wall rupture (240–244). *(Level of Evidence: B)*
3. Emergency CABG is recommended in patients with cardiogenic shock and who are suitable for CABG irrespective of the time interval from MI to onset of shock and time from MI to CABG (238,245–247). *(Level of Evidence: B)*
4. Emergency CABG is recommended in patients with life-threatening ventricular arrhythmias (believed to be ischemic in origin) in the presence of left main stenosis greater than or equal to 50% and/or 3-vessel CAD (248). *(Level of Evidence: C)*

CLASS IIa

1. The use of CABG is reasonable as a revascularization strategy in patients with multivessel CAD with recurrent angina or MI within the first 48 hours of STEMI presentation as an alternative to a more delayed strategy (235,237,239,249). *(Level of Evidence: B)*
2. Early revascularization with PCI or CABG is reasonable for selected patients greater than 75 years of age with ST-segment elevation or left bundle branch block who are suitable for revascularization irrespective of the time interval from MI to onset of shock (250–254). *(Level of Evidence: B)*

CLASS III: HARM

1. Emergency CABG should not be performed in patients with persistent angina and a small area of viable myocardium who are stable hemodynamically. *(Level of Evidence: C)*
2. Emergency CABG should not be performed in patients with no-reflow (successful epicardial reperfusion with unsuccessful microvascular reperfusion). *(Level of Evidence: C)*

See Online Data Supplement 5 for additional data on CABG in patients with acute myocardial infarction.

With the widespread use of fibrinolytic therapy or primary PCI in subjects with STEMI, emergency CABG is now reserved for those with 1) left main and/or 3-vessel CAD, 2) ongoing ischemia after successful or failed PCI, 3) coronary anatomy not amenable to PCI, 4) a mechanical complication of STEMI (241,255,256), and 5) cardiogenic shock (defined as hypotension [systolic arterial pressure <90 mm Hg for ≥ 30 minutes or need for supportive measures to maintain a systolic pressure ≥ 90 mm Hg], evidence of end-organ hypoperfusion, cardiac index ≤ 2.2 L/min/m^2, and pulmonary capillary wedge pressure ≥ 15 mm Hg) (245,247). In the SHOCK (Should We Emergently Revascularize Occluded Coronaries for Cardiogenic Shock) trial, 36% of patients randomly assigned to early revascularization therapy underwent emergency CABG (245). Although those who underwent emergency CABG were more likely to be diabetic and to have complex coronary anatomy than were those who had PCI, the survival rates of the 2 groups were similar (247). The outcomes of high-risk STEMI patients with cardiogenic shock undergoing emergency CABG suggest that CABG may be preferred to PCI in this patient population when complete revascularization cannot be accomplished with PCI (236,238,246).

The need for emergency CABG in subjects with STEMI is relatively uncommon, ranging from 3.2% to 10.9% (257,258). Of the 1,572 patients enrolled in the DANAMI-2 (Danish Multicenter Randomized Study on Thrombolytic Therapy Versus Acute Coronary Angioplasty in Acute Myocardial Infarction) study, only 50 (3.2%) underwent CABG within 30 days (30 patients initially treated with PCI and 20 given fibrinolysis), and only 3 patients (0.2%) randomly assigned to receive primary PCI underwent emergency CABG (257). Of the 1,100 patients who underwent coronary angiography in the PAMI-2 (Primary Angioplasty in Myocardial Infarction) trial, CABG was performed before hospital discharge in 120 (258).

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

The in-hospital mortality rate is higher in STEMI patients undergoing emergency CABG than in those undergoing it on a less urgent or a purely elective basis (239,257,259–264). In a study of 1,181 patients undergoing CABG, the in-hospital mortality rate increased as the patients' preoperative status worsened, ranging from 1.2% in those with stable angina to 26% in those with cardiogenic shock (265).

Although patients requiring emergency or urgent CABG after STEMI are at higher risk than those undergoing it electively, the optimal timing of CABG after STEMI is controversial. A retrospective study performed before the widespread availability of fibrinolysis and primary PCI reported an overall in-hospital mortality rate of 5.2% in 440 STEMI patients undergoing CABG as primary reperfusion therapy. Those undergoing CABG ≤6 hours after symptom onset had a lower in-hospital and long-term (10 years) mortality rate than those undergoing CABG >6 hours after symptom onset (237). Other studies have provided conflicting results, because of, at least in part, the lack of clear delineation between STEMI and NSTEMI patients in these large database reports (259,265). In an analysis of 9,476 patients hospitalized with an acute coronary syndrome (ACS) who underwent CABG during the index hospitalization, 1,344 (14%) were STEMI patients with shock or intra-aortic balloon placement preoperatively (264). These individuals had a mortality rate of 4% when CABG was performed on the third hospital day, which was lower than the mortality rates reported when CABG was performed earlier or later during the hospitalization (264). In studies in which the data from STEMI patients were analyzed separately with regard to the optimal timing of CABG, however, the results appear to be different. In 1 analysis of 44,365 patients who underwent CABG after MI (22,984 with STEMI; 21,381 with NSTEMI), the in-hospital mortality rate was similar in the 2 groups undergoing CABG <6 hours after diagnosis (12.5% and 11.5%, respectively), but it was higher in STEMI patients than in NSTEMI patients when CABG was performed 6 to 23 hours after diagnosis (13.6% versus 6.2%; p=0.006) (262). The groups had similar in-hospital mortality rates when CABG was performed at all later time points (1 to 7 days, 8 to 14 days, and ≥15 days after the acute event) (262). Similarly, in a study of 138 subjects with STEMI unresponsive to maximal nonsurgical therapy who underwent emergency CABG, the overall mortality rate was 8.7%, but it varied according to the time interval from symptom onset to time of operation. The mortality rate was 10.8% for patients undergoing CABG within 6 hours of the onset of symptoms, 23.8% in those undergoing CABG 7 to 24 hours after symptom onset, 6.7% in patients undergoing CABG from 1 to 3 days, 4.2% in those who underwent surgery from 4 to 7 days, and 2.4% after 8 days (266). In an analysis of data from 150 patients with STEMI who did not qualify for primary PCI and required CABG, the in-hospital mortality rate increased according to the time interval between symptom onset and surgery (239). The mortality rate was 6.1% for subjects who underwent CABG within 6 hours of pain onset, 50% in those who underwent CABG 7 to 23 hours after pain onset, and 7.1% in those who underwent CABG after 15 days (239). Lastly, in another study, the time interval of 6 hours was also found to be important in STEMI patients requiring CABG. The mean time from symptom onset to CABG was significantly shorter in survivors versus nonsurvivors (5.1±2.7 hours versus 11.4±3.2 hours; p<0.0007) (235). In patients with cardiogenic shock, the benefits of early revascularization were apparent across a wide time interval between 1) MI and the onset of shock and 2) MI and CABG. Therefore, although CABG exerts its most profound salutary effect when it is performed as soon as possible after MI and the appearance of shock, the time window in which it is beneficial is quite broad.

Apart from the timing of CABG, the outcomes of STEMI patients undergoing CABG depend on baseline demographic variables. Those with mechanical complications of STEMI (e.g., ventricular septal rupture or mitral regurgitation caused by papillary muscle rupture) have a high operative mortality rate (240–242,244,255,267). In a study of 641 subjects with ACS, 22 with evolving STEMI and 20 with a mechanical complication of STEMI were referred for emergency CABG; the 30-day mortality rate was 0% in those with evolving STEMI and 25% in those with a mechanical complication of STEMI (268). In those with mechanical complications, several variables were predictive of death, including advanced age, female sex, cardiogenic shock, the use of intra-aortic balloon counterpulsation preoperatively, pulmonary disease, renal insufficiency, and magnitude of elevation of the serum troponin concentration (235,239,263,265,266,269,270).

2.2.2. Life-Threatening Ventricular Arrhythmias: Recommendations

CLASS I

1. CABG is recommended in patients with resuscitated sudden cardiac death or sustained ventricular tachycardia thought to be caused by significant CAD (≥50% stenosis of left main coronary artery and/or ≥70% stenosis of 1, 2, or all 3 epicardial coronary arteries) and resultant myocardial ischemia (248,271,272). *(Level of Evidence: B)*

CLASS III: HARM

1. CABG should not be performed in patients with ventricular tachycardia with scar and no evidence of ischemia. *(Level of Evidence: C)*

See Online Data Supplement 6 for additional data on life-threatening ventricular arrhythmias.

Most studies evaluating the benefits of CABG in patients with ventricular arrhythmias have examined survivors of out-of-hospital cardiac arrest as well as patients with inducible ventricular tachycardia or fibrillation during electrophysiological study (272–274). In general, CABG has been more effective in reducing the occurrence of ventricular fibrillation than of ventricular tachycardia, because the mechanism of the latter is usually reentry with scarred

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

endocardium rather than ischemia. Observational studies have demonstrated a favorable prognosis of subjects undergoing CABG for ischemic ventricular tachycardia/fibrillation (248).

In survivors of cardiac arrest who have severe but operable CAD, CABG can suppress the appearance of arrhythmias, reduce subsequent episodes of cardiac arrest, and result in a good long-term outcome (271–273). It is particularly effective when an ischemic cause of the arrhythmia can be documented (for instance, when it occurs with exercise) (275). Still, because CABG may not alleviate all the factors that predispose to ventricular arrhythmias, concomitant insertion of an implantable cardioverter-defibrillator is often warranted (276). Similarly, continued inducibility or clinical recurrence of ventricular tachycardia after CABG usually requires an implantable cardioverter-defibrillator implantation.

Patients with depressed LV systolic function, advanced age, female sex, and increased CPB time are at higher risk for life-threatening arrhythmias in the early postoperative period. Given the poor short-term prognosis of those with these arrhythmias, mechanical and ischemic causes should be considered in the postoperative setting (277–279).

2.2.3. Emergency CABG After Failed PCI: Recommendations

CLASS I

1. Emergency CABG is recommended after failed PCI in the presence of ongoing ischemia or threatened occlusion with substantial myocardium at risk (280,281). *(Level of Evidence: B)*
2. Emergency CABG is recommended after failed PCI for hemodynamic compromise in patients without impairment of the coagulation system and without a previous sternotomy (280,282,283). *(Level of Evidence: B)*

CLASS IIa

1. Emergency CABG is reasonable after failed PCI for retrieval of a foreign body (most likely a fractured guidewire or stent) in a crucial anatomic location. *(Level of Evidence: C)*
2. Emergency CABG can be beneficial after failed PCI for hemodynamic compromise in patients with impairment of the coagulation system and without previous sternotomy. *(Level of Evidence: C)*

CLASS IIb

1. Emergency CABG might be considered after failed PCI for hemodynamic compromise in patients with previous sternotomy. *(Level of Evidence: C)*

CLASS III: HARM

1. Emergency CABG should not be performed after failed PCI in the absence of ischemia or threatened occlusion. *(Level of Evidence: C)*
2. Emergency CABG should not be performed after failed PCI if revascularization is impossible because of target anatomy or a no-reflow state. *(Level of Evidence: C)*

See Online Data Supplement 7 for additional data on CABG after failed PCI.

With widespread stent use as well as effective antiplatelet and antithrombotic therapies, emergency CABG after failed PCI is not commonly performed. In a 2009 analysis of data from almost 22,000 patients undergoing PCI at a single center, only 90 (0.4%) required CABG within 24 hours of PCI (281). A similarly low rate (≤0.8%) of emergency CABG after PCI has been reported by others (284–286). The indications for emergency CABG after PCI include 1) acute (or threatened) vessel closure, 2) coronary arterial dissection, 3) coronary arterial perforation (281), and 4) malfunction of PCI equipment (e.g., stent dislodgement, fractured guidewire). Subjects most likely to require emergency CABG after failed PCI are those with evolving STEMI, cardiogenic shock, 3-vessel CAD, or the presence of a type C coronary arterial lesion (defined as >2 cm in length, an excessively tortuous proximal segment, an extremely angulated segment, a total occlusion >3 months in duration, or a degenerated SVG that appears to be friable) (281).

In those in whom emergency CABG for failed PCI is performed, morbidity and mortality rates are increased compared with those undergoing elective CABG (287–289), resulting at least in part from the advanced age of many patients now referred for PCI, some of whom have multiple comorbid conditions and complex coronary anatomy. Several variables have been shown to be associated with increased perioperative morbidity and mortality rates, including 1) depressed LV systolic function (290), 2) recent ACS (290,291), 3) multivessel CAD and complex lesion morphology (291,292), 4) cardiogenic shock (281), 5) advanced patient age (293), 6) absence of angiographic collaterals (293), 7) previous PCI (294), and 8) a prolonged time delay in transfer to the operating room (293). In patients undergoing emergency CABG for failed PCI, an off-pump procedure may be associated with a reduced incidence of renal failure, need for intra-aortic balloon use, and reoperation for bleeding (283,295).

If complete revascularization is achieved with minimal delay in patients undergoing emergency CABG after failed PCI, long-term prognosis is similar to that of subjects undergoing elective CABG (280,282,296). In-hospital morbidity and mortality rates in women (297) and the elderly (298) undergoing emergency CABG for failed PCI are relatively high, but the long-term outcomes in these individuals are comparable to those achieved in men and younger patients.

2.2.4. CABG in Association With Other Cardiac Procedures: Recommendations

CLASS I

1. CABG is recommended in patients undergoing noncoronary cardiac surgery with greater than or equal to 50% luminal diameter narrowing of the left main coronary artery or greater than or equal to 70% luminal diameter narrowing of other major coronary arteries. *(Level of Evidence: C)*

CLASS IIa

1. The use of the LIMA is reasonable to bypass a significantly narrowed LAD artery in patients undergoing noncoronary cardiac surgery. *(Level of Evidence: C)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

2. CABG of moderately diseased coronary arteries (>50% luminal diameter narrowing) is reasonable in patients undergoing noncoronary cardiac surgery. (*Level of Evidence: C*)

3. CAD Revascularization

Recommendations and text in this section are the result of extensive collaborative discussions between the PCI and CABG writing committees, as well as key members of the Stable Ischemic Heart Disease (SIHD) and UA/NSTEMI writing committees. Certain issues, such as older versus more contemporary studies, primary analyses versus subgroup analyses, and prospective versus post hoc analyses, have been carefully weighed in designating COR and LOE; they are addressed in the appropriate corresponding text. The goals of revascularization for patients with CAD are to 1) to improve survival and 2) to relieve symptoms.

Revascularization recommendations in this section are predominantly based on studies of patients with symptomatic SIHD and should be interpreted in this context. As discussed later in this section, recommendations on the type of revascularization are, in general, applicable to patients with UA/NSTEMI. In some cases (e.g., unprotected left main CAD), specific recommendations are made for patients with UA/NSTEMI or STEMI.

Historically, most studies of revascularization have been based on and reported according to angiographic criteria. Most studies have defined a "significant" stenosis as ≥70% diameter narrowing; therefore, for revascularization decisions and recommendations in this section, a "significant" stenosis has been defined as ≥70% diameter narrowing (≥50% for left main CAD). Physiological criteria, such as an assessment of fractional flow reserve, has been used in deciding when revascularization is indicated. Thus, for recommendations on revascularization in this section, coronary stenoses with fractional flow reserve ≤0.80 can also be considered "significant" (299,300).

As noted, the revascularization recommendations have been formulated to address issues related to 1) improved survival and/or 2) improved symptoms. When one method of revascularization is preferred over the other for improved survival, this consideration, in general, takes precedence over improved symptoms. When discussing options for revascularization with the patient, he or she should understand when the procedure is being performed in an attempt to improve symptoms, survival, or both.

Although some results from the SYNTAX (Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery) study are best characterized as subgroup analyses and "hypothesis generating," SYNTAX nonetheless represents the latest and most comprehensive comparison of contemporary PCI and CABG (301,302). Therefore, the results of SYNTAX have been considered appropriately when formulating our revascularization recommendations. Although the limitations of using the SYNTAX score for certain revascularization recommendations are recognized, the SYNTAX score is a reasonable surrogate for the extent of CAD and its complexity and serves as important information that should be considered when making revascularization decisions. Recommendations that refer to SYNTAX scores use them as surrogates for the extent and complexity of CAD.

Revascularization recommendations to improve survival and symptoms are given in the following text and summarized in Tables 2 and 3. References to studies comparing revascularization with medical therapy are presented when available for each anatomic subgroup.

See Online Data Supplements 8 and 9 for additional data regarding the survival and symptomatic benefits with CABG or PCI for different anatomic subsets.

3.1. Heart Team Approach to Revascularization Decisions: Recommendations

CLASS I

1. A Heart Team approach to revascularization is recommended in patients with unprotected left main or complex CAD (302–304). (*Level of Evidence: C*)

CLASS IIa

1. Calculation of the STS and SYNTAX scores is reasonable in patients with unprotected left main and complex CAD (301,302,305–310). (*Level of Evidence: B*)

One protocol used in RCTs (302–304,311) often involves a multidisciplinary approach referred to as the Heart Team. Composed of an interventional cardiologist and a cardiac surgeon, the Heart Team 1) reviews the patient's medical condition and coronary anatomy, 2) determines that PCI and/or CABG are technically feasible and reasonable, and 3) discusses revascularization options with the patient before a treatment strategy is selected. Support for using a Heart Team approach comes from reports that patients with complex CAD referred specifically for PCI or CABG in concurrent trial registries have lower mortality rates than those randomly assigned to PCI or CABG in controlled trials (303,304).

The SIHD, PCI, and CABG guideline writing committees endorse a Heart Team approach in patients with unprotected left main CAD and/or complex CAD in whom the optimal revascularization strategy is not straightforward. A collaborative assessment of revascularization options, or the decision to treat with GDMT without revascularization, involving an interventional cardiologist, a cardiac surgeon, and (often) the patient's general cardiologist, followed by discussion with the patient about treatment options, is optimal. Particularly in patients with SIHD and unprotected left main and/or complex CAD for whom a revascularization strategy is not straightforward, an approach has been endorsed that involves terminating the procedure after diagnostic coronary angiography is completed; this allows a thorough discussion and affords both the interventional cardiologist and cardiac surgeon the opportunity to discuss

Table 2. Revascularization to Improve Survival Compared With Medical Therapy

Anatomic Setting	COR	LOE	References
UPLM or complex CAD			
CABG and PCI	I—Heart Team approach recommended	C	(302–304)
CABG and PCI	IIa—Calculation of the STS and SYNTAX scores	B	(301,302,305–310)
UPLM*			
CABG	I	B	(312–318)
PCI	IIa—For SIHD when both of the following are present: • Anatomic conditions associated with a low risk of PCI procedural complications and a high likelihood of good long-term outcome (e.g., a low SYNTAX score of ≤22, ostial or trunk left main CAD) • Clinical characteristics that predict a significantly increased risk of adverse surgical outcomes (e.g., STS-predicted risk of operative mortality ≥5%)	B	(301,305,307,311,319–336)
	IIa—For UA/NSTEMI if not a CABG candidate	B	(301,324–327,332,333, 335–337)
	IIa—For STEMI when distal coronary flow is TIMI flow grade <3 and PCI can be performed more rapidly and safely than CABG	C	(321,338,339)
	IIb—For SIHD when *both* of the following are present: • Anatomic conditions associated with a low to intermediate risk of PCI procedural complications and intermediate to high likelihood of good long-term outcome (e.g., low–intermediate SYNTAX score of <33, bifurcation left main CAD) • Clinical characteristics that predict an increased risk of adverse surgical outcomes (e.g., moderate–severe COPD, disability from prior stroke, or prior cardiac surgery; STS-predicted risk of operative mortality >2%)	B	(301,305,307,311, 319–336,340)
	III: Harm—For SIHD in patients (versus performing CABG) with unfavorable anatomy for PCI and who are good candidates for CABG	B	(301,305,307,312–320)
3-vessel disease with or without proximal LAD artery disease*			
CABG	I	B	(314,318,341–344)
	IIa—It is reasonable to choose CABG over PCI in patients with complex 3-vessel CAD (e.g., SYNTAX >22) who are good candidates for CABG	B	(320,334,343,359–360)
PCI	IIb—Of uncertain benefit	B	(314,341,343,370).
2-vessel disease with proximal LAD artery disease*			
CABG	I	B	(314,318,341–344)
PCI	IIb—Of uncertain benefit	B	(314,341,343,370)
2-vessel disease without proximal LAD artery disease*			
CABG	IIa—With extensive ischemia	B	(348–351)
	IIb—Of uncertain benefit without extensive ischemia	C	(343)
PCI	IIb—Of uncertain benefit	B	(314,341,343,370)
1-vessel proximal LAD artery disease			
CABG	IIa—With LIMA for long-term benefit	B	(87,88,318,343)
PCI	IIb—Of uncertain benefit	B	(314,341,343,370)
1-vessel disease without proximal LAD artery involvement			
CABG	III: Harm	B	(318,341,348,349, 382–386)
PCI	III: Harm	B	(318,341,348,349, 382–386)
LV dysfunction			
CABG	IIa—EF 35% to 50%	B	(318,352–356)
CABG	IIb—EF <35% without significant left main CAD	B	(318,352–356,371,372)
PCI	Insufficient data		N/A
Survivors of sudden cardiac death with presumed ischemia-mediated VT			
CABG	I	B	(271,345,347)
PCI	I	C	(345)
No anatomic or physiological criteria for revascularization			
CABG	III: Harm	B	(318,341,348,349,382–386)
PCI	III: Harm	B	(318,341,348,349,382–386)

In patients with multivessel disease who also have diabetes, it is reasonable to choose CABG (with LIMA) over PCI (350,362–369) *(Class IIa/LOE: B).

CABG indicates coronary artery bypass graft; CAD, coronary artery disease; COPD, chronic obstructive pulmonary disease; COR, class of recommendation; EF, ejection fraction; LAD, left anterior descending; LIMA, left internal mammary artery; LOE, level of evidence; LV, left ventricular; N/A, not applicable; PCI, percutaneous coronary intervention; SIHD, stable ischemic heart disease; STEMI, ST-elevation myocardial infarction; STS, Society of Thoracic Surgeons; SYNTAX, Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery; TIMI, Thrombolysis In Myocardial Infarction; UA/NSTEMI, unstable angina/non–ST-elevation myocardial infarction; UPLM, unprotected left main disease; and VT, ventricular tachycardia.

Table 3. Revascularization to Improve Symptoms With Significant Anatomic (≥50% Left Main or ≥70% Non–Left Main CAD) or Physiological (FFR≤0.80) Coronary Artery Stenoses

Clinical Setting	COR	LOE	References
≥1 significant stenoses amenable to revascularization and unacceptable angina despite GDMT	I—CABG I—PCI	A	(370,387–396)
≥1 significant stenoses and unacceptable angina in whom GDMT cannot be implemented because of medication contraindications, adverse effects, or patient preferences	IIa—CABG IIa—PCI	C	N/A
Previous CABG with ≥1 significant stenoses associated with ischemia and unacceptable angina despite GDMT	IIa—PCI	C	(374,377,380)
	IIb—CABG	C	(381)
Complex 3-vessel CAD (e.g., SYNTAX score >22) with or without involvement of the proximal LAD artery and a good candidate for CABG	IIa—CABG preferred over PCI	B	(320,343,359–361)
Viable ischemic myocardium that is perfused by coronary arteries that are not amenable to grafting	IIb—TMR as an adjunct to CABG	B	(397–401)
No anatomic or physiologic criteria for revascularization	III: Harm—CABG III: Harm—PCI	C	N/A

CABG indicates coronary artery bypass graft; CAD, coronary artery disease; COR, class of recommendation; FFR, fractional flow reserve; GDMT, guideline-directed medical therapy; LOE, level of evidence; N/A, not applicable; PCI, percutaneous coronary intervention; SYNTAX, Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery; and TMR, transmyocardial laser revascularization.

revascularization options with the patient. Because the STS score and the SYNTAX score have been shown to predict adverse outcomes in patients undergoing CABG and PCI, respectively, calculation of these scores is often useful in making revascularization decisions (301,302,305–310).

3.2. Revascularization to Improve Survival: Recommendations

Left Main CAD Revascularization

CLASS I

1. CABG to improve survival is recommended for patients with significant (≥50% diameter stenosis) left main coronary artery stenosis (312–318). *(Level of Evidence: B)*

CLASS IIa

1. PCI to improve survival is reasonable as an alternative to CABG in selected stable patients with significant (≥50% diameter stenosis) unprotected left main CAD with: 1) anatomic conditions associated with a low risk of PCI procedural complications and a high likelihood of good long-term outcome (e.g., a low SYNTAX score [≤22], ostial or trunk left main CAD); and 2) clinical characteristics that predict a significantly increased risk of adverse surgical outcomes (e.g., STS-predicted risk of operative mortality ≥5%) (301,305,307,311,319–336). *(Level of Evidence: B)*
2. PCI to improve survival is reasonable in patients with UA/NSTEMI when an unprotected left main coronary artery is the culprit lesion and the patient is not a candidate for CABG (301,324–327,332, 333,335–337). *(Level of Evidence: B)*
3. PCI to improve survival is reasonable in patients with acute STEMI when an unprotected left main coronary artery is the culprit lesion, distal coronary flow is less than Thrombolysis In Myocardial Infarction grade 3, and PCI can be performed more rapidly and safely than CABG (321,338,339). *(Level of Evidence: C)*

CLASS IIb

1. PCI to improve survival may be reasonable as an alternative to CABG in selected stable patients with significant (≥50% diameter stenosis) unprotected left main CAD with: 1) anatomic conditions associated with a low to intermediate risk of PCI procedural complications and an intermediate to high likelihood of good long-term outcome (e.g., low–intermediate SYNTAX score of <33, bifurcation left main CAD); and 2) clinical characteristics that predict an increased risk of adverse surgical outcomes (e.g., moderate–severe chronic obstructive pulmonary disease, disability from previous stroke, or previous cardiac surgery; STS-predicted risk of operative mortality >2%) (301,305,307,311,319–336,340). *(Level of Evidence: B)*

CLASS III: HARM

1. PCI to improve survival should not be performed in stable patients with significant (≥50% diameter stenosis) unprotected left main CAD who have unfavorable anatomy for PCI and who are good candidates for CABG (301,305,307,312–320). *(Level of Evidence: B)*

Non–Left Main CAD Revascularization

CLASS I

1. CABG to improve survival is beneficial in patients with significant (≥70% diameter) stenoses in 3 major coronary arteries (with or without involvement of the proximal LAD artery) or in the proximal LAD plus 1 other major coronary artery (314,318,341–344). *(Level of Evidence: B)*
2. CABG or PCI to improve survival is beneficial in survivors of sudden cardiac death with presumed ischemia-mediated ventricular tachycardia caused by significant (≥70% diameter) stenosis in a major coronary artery. *(CABG Level of Evidence: B [271,345,347]; PCI Level of Evidence: C [345])*

CLASS IIa

1. CABG to improve survival is reasonable in patients with significant (≥70% diameter) stenoses in 2 major coronary arteries with severe or extensive myocardial ischemia (e.g., high-risk criteria on stress testing, abnormal intracoronary hemodynamic evaluation, or >20% perfusion defect by myocardial perfusion stress imaging) or target vessels supplying a large area of viable myocardium (348–351). *(Level of Evidence: B)*
2. CABG to improve survival is reasonable in patients with mild-moderate LV systolic dysfunction (EF 35% to 50%) and significant (≥70% diameter stenosis) multivessel CAD or proximal LAD coronary artery stenosis, when viable myocardium is present in the region of intended revascularization (318,352–356). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

3. CABG with a LIMA graft to improve survival is reasonable in patients with significant (≥70% diameter) stenosis in the proximal LAD artery and evidence of extensive ischemia (87,88,318,343). *(Level of Evidence: B)*
4. It is reasonable to choose CABG over PCI to improve survival in patients with complex 3-vessel CAD (e.g., SYNTAX score >22), with or without involvement of the proximal LAD artery, who are good candidates for CABG (320,334,343,359–360). *(Level of Evidence: B)*
5. CABG is probably recommended in preference to PCI to improve survival in patients with multivessel CAD and diabetes mellitus, particularly if a LIMA graft can be anastomosed to the LAD artery (350,362–369). *(Level of Evidence: B)*

CLASS IIb

1. The usefulness of CABG to improve survival is uncertain in patients with significant (≥70%) stenoses in 2 major coronary arteries not involving the proximal LAD artery and without extensive ischemia (343). *(Level of Evidence: C)*
2. The usefulness of PCI to improve survival is uncertain in patients with 2- or 3-vessel CAD (with or without involvement of the proximal LAD artery) or 1-vessel proximal LAD disease (314,341,343,370). *(Level of Evidence: B)*
3. CABG might be considered with the primary or sole intent of improving survival in patients with SIHD with severe LV systolic dysfunction (EF <35%) whether or not viable myocardium is present (318,352–356,371,372). *(Level of Evidence: B)*
4. The usefulness of CABG or PCI to improve survival is uncertain in patients with previous CABG and extensive anterior wall ischemia on noninvasive testing (373–381). *(Level of Evidence: B)*

CLASS III: HARM

1. CABG or PCI should not be performed with the primary or sole intent to improve survival in patients with SIHD with 1 or more coronary stenoses that are not anatomically or functionally significant (e.g., <70% diameter non–left main coronary artery stenosis, fractional flow reserve >0.80, no or only mild ischemia on noninvasive testing), involve only the left circumflex or right coronary artery, or subtend only a small area of viable myocardium (318,341,348,349, 382–386). *(Level of Evidence: B)*

3.3. Revascularization to Improve Symptoms: Recommendations

CLASS I

1. CABG or PCI to improve symptoms is beneficial in patients with 1 or more significant (≥70% diameter) coronary artery stenoses amenable to revascularization and unacceptable angina despite GDMT (370,387–396). *(Level of Evidence: A)*

CLASS IIa

1. CABG or PCI to improve symptoms is reasonable in patients with 1 or more significant (≥70% diameter) coronary artery stenoses and unacceptable angina for whom GDMT cannot be implemented because of medication contraindications, adverse effects, or patient preferences. *(Level of Evidence: C)*
2. PCI to improve symptoms is reasonable in patients with previous CABG, 1 or more significant (≥70% diameter) coronary artery stenoses associated with ischemia, and unacceptable angina despite GDMT (374,377,380). *(Level of Evidence: C)*
3. It is reasonable to choose CABG over PCI to improve symptoms in patients with complex 3-vessel CAD (e.g., SYNTAX score >22), with or without involvement of the proximal LAD artery, who are good candidates for CABG (320,334,343,359–360). *(Level of Evidence: B)*

CLASS IIb

1. CABG to improve symptoms might be reasonable for patients with previous CABG, 1 or more significant (≥70% diameter) coronary artery stenoses not amenable to PCI, and unacceptable angina despite GDMT (381). *(Level of Evidence: C)*
2. Transmyocardial laser revascularization (TMR) performed as an adjunct to CABG to improve symptoms may be reasonable in patients with viable ischemic myocardium that is perfused by arteries that are not amenable to grafting (397–401). *(Level of Evidence: B)*

CLASS III: HARM

1. CABG or PCI to improve symptoms should not be performed in patients who do not meet anatomic (≥50% left main or ≥70% non–left main stenosis) or physiological (e.g., abnormal fractional flow reserve) criteria for revascularization. *(Level of Evidence: C)*

3.4. CABG Versus Contemporaneous Medical Therapy

In the 1970s and 1980s, 3 RCTs established the survival benefit of CABG compared with contemporaneous (although minimal by current standards) medical therapy without revascularization in certain subjects with stable angina: the Veterans Affairs Cooperative Study (402), European Coronary Surgery Study (344), and CASS (Coronary Artery Surgery Study) (403). Subsequently, a 1994 meta-analysis of 7 studies that randomized a total of 2,649 patients to medical therapy for CABG (318) showed that CABG offered a survival advantage over medical therapy for patients with left main or 3-vessel CAD. The studies also established that CABG is more effective than medical therapy at relieving anginal symptoms. These studies have been replicated only once during the past decade. In MASS II (Medicine, Angioplasty, or Surgery Study II), patients with multivessel CAD who were treated with CABG were less likely than those treated with medical therapy to have a subsequent MI, need additional revascularization, or experience cardiac death in the 10 years after randomization (392).

Surgical techniques and medical therapy have improved substantially during the intervening years. As a result, if CABG were to be compared with GDMT in RCTs today, the relative benefits for survival and angina relief observed several decades ago might no longer be observed. Conversely, the concurrent administration of GDMT may substantially improve long-term outcomes in patients treated with CABG in comparison with those receiving medical therapy alone. In the BARI 2D (Bypass Angioplasty Revascularization Investigation 2 Diabetes) trial of patients with diabetes mellitus, no significant difference in risk of mortality in the cohort of patients randomized to GDMT plus CABG or GDMT alone was observed, although the study was not powered for this endpoint, excluded patients with significant left main CAD, and included only a small percentage of patients with proximal LAD artery disease or LV ejection fraction (LVEF) <0.50 (404). The PCI and CABG guideline writing committees endorse the performance of the ISCHEMIA (International Study of Comparative Health Effectiveness with Medical and Invasive Approaches) trial,

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

which will provide contemporary data on the optimal management strategy (medical therapy or revascularization with CABG or PCI) of patients with SIHD, including multivessel CAD, and moderate to severe ischemia.

3.5. PCI Versus Medical Therapy

Although contemporary interventional treatments have lowered the risk of restenosis compared with earlier techniques, meta-analyses have failed to show that the introduction of bare-metal stents (BMS) confers a survival advantage over balloon angioplasty (405–407) or that the use of drug-eluting stents (DES) confers a survival advantage over BMS (407,408).

No study to date has demonstrated that PCI in patients with SIHD improves survival rates (314,341,343,370,404,407,409–412). Neither COURAGE (Clinical Outcomes Utilizing Revascularization and Aggressive Drug Evaluation) (370) nor BARI 2D (404), which treated all patients with contemporary optimal medical therapy, demonstrated any survival advantage with PCI, although these trials were not specifically powered for this endpoint. Although 1 large analysis evaluating 17 RCTs of PCI versus medical therapy (including 5 trials of subjects with ACS) found a 20% reduction in death with PCI compared with medical therapy (411), 2 other large analyses did not (407,410). An evaluation of 13 studies reporting the data from 5,442 patients with nonacute CAD showed no advantage of PCI over medical therapy for the individual endpoints of all-cause death, cardiac death or MI, or nonfatal MI (412). Evaluation of 61 trials of PCI conducted over several decades shows that despite improvements in PCI technology and pharmacotherapy, PCI has not been demonstrated to reduce the risk of death or MI in patients without recent ACS (407).

The findings from individual studies and systematic reviews of PCI versus medical therapy can be summarized as follows:

- PCI reduces the incidence of angina (370,387,392,395,396,413).
- PCI has not been demonstrated to improve survival in stable patients (407,409,410).
- PCI may increase the short-term risk of MI (370,409,413,414).
- PCI does not lower the long-term risk of MI (370,404,407,409,410,414).

3.6. CABG Versus PCI

The results of 26 RCTs comparing CABG and PCI have been published: Of these, 9 compared CABG with balloon angioplasty (363,393,415–429), 14 compared CABG with BMS implantation (376,430–447), and 3 compared CABG with DES implantation (302,448,449).

3.6.1. CABG Versus Balloon Angioplasty or BMS

A systematic review of the 22 RCTs comparing CABG with balloon angioplasty or BMS implantation concluded the following (450):

1. Survival was similar for CABG and PCI (with balloon angioplasty or BMS) at 1 year and 5 years. Survival was similar for CABG and PCI in subjects with 1-vessel CAD (including those with disease of the proximal portion of the LAD artery) or multivessel CAD.
2. Incidence of MI was similar at 5 years after randomization.
3. Procedural stroke occurred more commonly with CABG than with PCI (1.2% versus 0.6%).
4. Relief of angina was accomplished more effectively with CABG than with PCI 1 year after randomization and 5 years after randomization.
5. During the first year after randomization, repeat coronary revascularization was performed less often after CABG than after PCI (3.8% versus 26.5%). This was also demonstrated after 5 years of follow-up (9.8% versus 46.1%). This difference was more pronounced with balloon angioplasty than with BMS.

A collaborative analysis of data from 10 RCTs comparing CABG with balloon angioplasty (6 trials) or with BMS implantation (4 trials) (451) permitted subgroup analyses of the data from the 7,812 patients. No difference was noted with regard to mortality rate 5.9 years after randomization or the composite endpoint of death or MI. Repeat revascularization and angina were noted more frequently in those treated with balloon angioplasty or BMS implantation (451). The major new observation of this analysis was that CABG was associated with better outcomes in patients with diabetes mellitus and in those >65 years old. Of interest, the relative outcomes of CABG and PCI were not influenced by other patient characteristics, including the number of diseased coronary arteries.

The aforementioned meta-analysis and systematic review (450,451) comparing CABG and balloon angioplasty or BMS implantation were limited in several ways.

1. Many trials did not report outcomes for other important patient subsets. For example, the available data are insufficient to determine if race, obesity, renal dysfunction, peripheral artery disease (PAD), or previous coronary revascularization affected the comparative outcomes of CABG and PCI.
2. Most of the patients enrolled in these trials were male, and most had 1- or 2-vessel CAD and normal LV systolic function (EF >50%)—subjects known to be unlikely to derive a survival benefit and less likely to experience complications after CABG (318).
3. The patients enrolled in these trials represented only a small fraction (generally <5% to 10%) of those who were screened. For example, most screened patients with

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

1-vessel CAD and many with 3-vessel CAD were not considered for randomization.

See Online Data Supplements 10 and 11 for additional data comparing CABG with PCI.

3.6.2. CABG Versus DES

Although the results of 9 observational studies comparing CABG and DES implantation have been published (320,452–459), most of them had short (12 to 24 months) follow-up periods. In a meta-analysis of 24,268 patients with multivessel CAD treated with CABG or DES (460), the incidences of death and MI were similar for the 2 procedures, but the frequency with which repeat revascularization was performed was roughly 4 times higher after DES implantation. Only 1 large RCT comparing CABG and DES implantation has been published. The SYNTAX trial randomly assigned 1,800 patients (of a total of 4,337 who were screened) to receive DES or CABG (302,334). Major adverse cardiac events (MACE), a composite of death, stroke, MI, or repeat revascularization during the 3 years after randomization, occurred in 20.2% of CABG patients and 28.0% of those undergoing DES implantation ($p<0.001$). The rates of death and stroke were similar; however, MI (3.6% for CABG; 7.1% for DES) and repeat revascularization (10.7% for CABG; 19.7% for DES) were more likely to occur with DES implantation (334).

In SYNTAX, the extent of CAD was assessed using the SYNTAX score, which is based on the location, severity, and extent of coronary stenoses, with a low score indicating less complicated anatomic CAD. In post hoc analyses, a low score was defined as ≤22; intermediate 23 to 32; and high, ≥33. The occurrence of MACE correlated with the SYNTAX score for DES patients but not for those undergoing CABG. At 12-month follow-up, the primary endpoint was similar for CABG and DES in those with a low SYNTAX score. In contrast, MACE occurred more often after DES implantation than after CABG in those with an intermediate or high SYNTAX score (302). At 3 years of follow-up, the mortality rate was greater in subjects with 3-vessel CAD treated with PCI than in those treated with CABG (6.2% versus 2.9%). The differences in MACE between those treated with PCI or CABG increased with an increasing SYNTAX score (Figure 1) (334).

Although the utility of using a SYNTAX score in everyday clinical practice remains uncertain, it seems reasonable to conclude from SYNTAX and other data that outcomes of patients undergoing PCI or CABG in those with relatively uncomplicated and lesser degrees of CAD are comparable, whereas in those with complex and diffuse CAD, CABG appears to be preferable (334).

See Online Data Supplements 12 and 13 for additional data comparing CABG with DES.

3.7. Left Main CAD

3.7.1. CABG or PCI Versus Medical Therapy for Left Main CAD

CABG confers a survival benefit over medical therapy in patients with left main CAD. Subgroup analyses from RCTs performed 3 decades ago included 91 patients with left main CAD in the Veterans Administration Cooperative Study (316). A meta-analysis of these trials demonstrated a 66% RR reduction in mortality with CABG, with the benefit extending to 10 years (318). The CASS Registry (312) contained data from 1,484 patients with ≥50% left main CAD initially treated surgically or nonsurgically. Median survival duration was 13.3 years in the surgical group and 6.6 years in the medical group. The survival benefit of CABG over medical therapy appeared to extend to 53 asymptomatic patients with left main CAD in the CASS Registry (317). Other therapies that subsequently have been shown to be associated with improved long-term

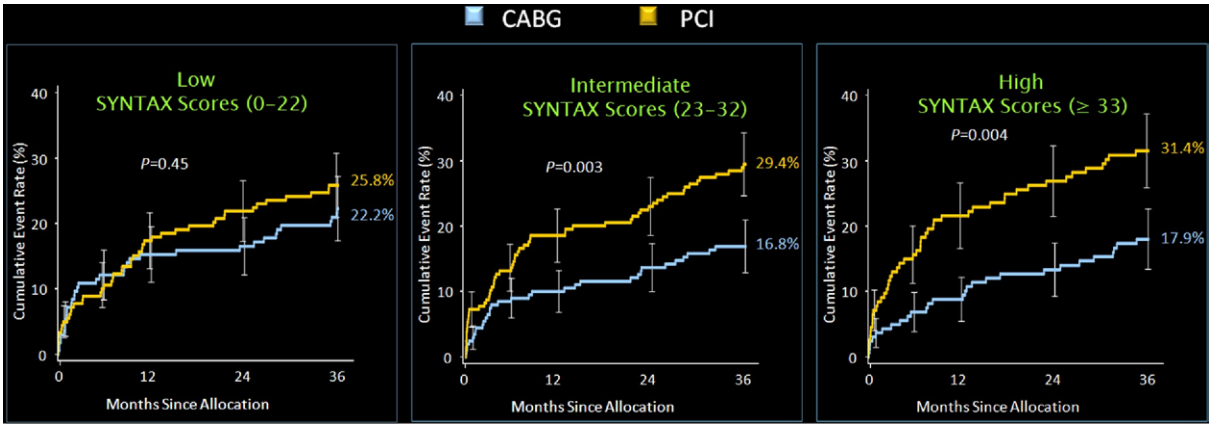

Figure 1. Cumulative Incidence of MACE in Patients With 3-Vessel CAD Based on SYNTAX Score at 3-Year Follow-Up in the SYNTAX Trial Treated With Either CABG or PCI

CABG indicates coronary artery bypass graft; CAD, coronary artery disease; MACE, major adverse cardiovascular event; PCI, percutaneous coronary intervention; and SYNTAX, Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery. Adapted with permission from Kappetein (334).

ARTICLE IN PRESS

outcome, such as the use of aspirin, statins, and IMA grafting, were not widely used in that era.

RCTs and subgroup analyses that compare PCI with medical therapy in patients with "unprotected" left main CAD do not exist.

3.7.2. Studies Comparing PCI Versus CABG for Left Main CAD

Of all subjects undergoing coronary angiography, approximately 4% are found to have left main CAD (463), >80% of whom have significant (≥70% diameter) stenoses in other epicardial coronary arteries.

Published cohort studies have found that major clinical outcomes are similar with PCI or CABG 1 year after revascularization and that mortality rates are similar at 1, 2, and 5 years of follow-up; however, the risk of needing target-vessel revascularization is significantly higher with stenting than with CABG.

In the SYNTAX trial, 45% of screened patients with unprotected left main CAD had complex diseases that prevented randomization; 89% of these underwent CABG (301,302). In addition, 705 of the 1,800 patients who were randomized had revascularization for unprotected left main CAD. The majority of patients with left main CAD and a low SYNTAX score had isolated left main CAD or left main CAD plus 1-vessel CAD; the majority of those with an intermediate score had left main CAD plus 2-vessel CAD; and most of those with a high SYNTAX score had left main CAD plus 3-vessel CAD. At 1 year, rates of all-cause death and MACE were similar for the 2 groups (301). Repeat revascularization rates were higher in the PCI group than the CABG group (11.8% versus 6.5%), but stroke occurred more often in the CABG group (2.7% versus 0.3%). At 3 years of follow-up, the incidence of death in those undergoing left main CAD revascularization with low or intermediate SYNTAX scores (≤32) was 3.7% after PCI and 9.1% after CABG (p=0.03), whereas in those with a high SYNTAX score (≥33) the incidence of death after 3 years was 13.4% after PCI and 7.6% after CABG (p=0.10) (334). Because the primary endpoint of SYNTAX was not met (i.e., noninferiority comparison of CABG and PCI), these subgroup analyses need to be considered in that context.

In the LE MANS (Study of Unprotected Left Main Stenting Versus Bypass Surgery) trial (311), 105 patients with left main CAD were randomized to receive PCI or CABG. Although a low proportion of patients treated with PCI received DES (35%) and a low proportion of patients treated with CABG received IMA grafts (72%), the outcomes at 30 days and 1 year were similar between the groups. In the PRECOMBAT (Premier of Randomized Comparison of Bypass Surgery versus Angioplasty Using Sirolimus-Eluting Stent in Patients with Left Main Coronary Artery Disease) trial of 600 patients with left main disease, the composite endpoint of death, MI, or stroke at 2 years occurred in 4.4% of patients treated with PCI and 4.7% of patients treated with CABG, but ischemia-driven target-vessel revascularization was more often required in the patients treated with PCI (9.0% versus 4.2%) (340).

The results from these 3 RCTs suggest (but do not definitively prove) that major clinical outcomes in *selected* patients with left main CAD are similar with CABG and PCI at 1- to 2-year follow-up, but repeat revascularization rates are higher after PCI than after CABG. RCTs with extended follow-up of ≥5 years are required to provide definitive conclusions about the optimal treatment of left main CAD. In a meta-analysis of 8 cohort studies and 2 RCTs (329), death, MI, and stroke occurred with similar frequency in the PCI- and CABG-treated patients at 1, 2, and 3 years of follow-up. Target-vessel revascularization was performed more often in the PCI group at 1 year (OR: 4.36), 2 years (OR: 4.20), and 3 years (OR: 3.30).

See Online Data Supplements 14 to 19 for additional data comparing PCI with CABG for left main CAD.

3.7.3. Revascularization Considerations for Left Main CAD

Although CABG has been considered the "gold standard" for unprotected left main CAD revascularization, more recently PCI has emerged as a possible alternative mode of revascularization in carefully selected patients. Lesion location is an important determinant when considering PCI for unprotected left main CAD. Stenting of the left main ostium or trunk is more straightforward than treating distal bifurcation or trifurcation stenoses, which generally requires a greater degree of operator experience and expertise (464). In addition, PCI of bifurcation disease is associated with higher restenosis rates than when disease is confined to the ostium or trunk (327,465). Although lesion location influences technical success and long-term outcomes after PCI, location exerts a negligible influence on the success of CABG. In subgroup analyses, patients with left main CAD and a SYNTAX score ≥33 with more complex or extensive CAD had a higher mortality rate with PCI than with CABG (334). Physicians can estimate operative risk for all CABG candidates by using a standard instrument, such as the risk calculator from the STS database. The above considerations are important factors when choosing among revascularization strategies for unprotected left main CAD and have been factored into revascularization recommendations. Use of a Heart Team approach has been recommended in cases in which the choice of revascularization is not straightforward. As discussed in Section 3.9.7, the ability of the patient to tolerate and comply with dual antiplatelet therapy (DAPT) is also an important consideration in revascularization decisions.

The 2005 PCI guidelines (466) recommended routine angiographic follow-up 2 to 6 months after stenting for uprotected left main CAD. However, because angiography has limited ability to predict stent thrombosis and the

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

results of SYNTAX suggest good intermediate-term results for PCI in subjects with left main CAD, this recommendation was removed in the 2009 STEMI/PCI focused update (467).

Experts have recommended immediate PCI for unprotected left main CAD in the setting of STEMI (339). The impetus for such a strategy is greatest when the left main CAD is the site of the culprit lesion, antegrade coronary flow is diminished [e.g., Thrombolysis In Myocardial Infarction flow grade 0, 1, or 2], the patient is hemodynamically unstable, and it is believed that PCI can be performed more quickly than CABG. When possible, the interventional cardiologist and cardiac surgeon should decide together on the optimal form of revascularization for these subjects, although it is recognized that these patients are usually critically ill and therefore not amenable to a prolonged deliberation or discussion of treatment options.

3.8. Proximal LAD Artery Disease

A cohort study (341) and a meta-analysis (318) from the 1990s suggested that CABG confers a survival advantage over contemporaneous medical therapy for patients with disease in the proximal segment of the LAD artery. Cohort studies and RCTs (318,420,432,433,435,448,468–470) as well as collaborative- and meta-analyses (451,471–473) showed that PCI and CABG result in similar survival rates in these patients.

See Online Data Supplement 20 for additional data regarding proximal LAD artery revascularization.

3.9. Clinical Factors That May Influence the Choice of Revascularization

3.9.1. Diabetes Mellitus

An analysis performed in 2009 of data on 7,812 patients (1,233 with diabetes) in 10 RCTs demonstrated a worse long-term survival rate in patients with diabetes mellitus after balloon angioplasty or BMS implantation than after CABG (451). The BARI 2D trial (404) randomly assigned 2,368 patients with type 2 diabetes and CAD to undergo intensive medical therapy or prompt revascularization with PCI or CABG, according to whichever was thought to be more appropriate. By study design, those with less extensive CAD more often received PCI, whereas those with more extensive CAD were more likely to be treated with CABG. The study was not designed to compare PCI with CABG. At 5-year follow-up, no difference in rates of survival or MACE between the medical therapy group and those treated with revascularization was noted. In the PCI stratum, no significant difference in MACE between medical therapy and revascularization was demonstrated (DES in 35%; BMS in 56%); in the CABG stratum, MACE occurred less often in the revascularization group. One-year follow-up data from the SYNTAX study demonstrated a higher rate of repeat revascularization in patients with diabetes mellitus treated with PCI than with CABG, driven by a tendency for higher repeat revascularization rates in those with higher SYNTAX scores undergoing PCI (364). In summary, in subjects requiring revascularization for multivessel CAD, current evidence supports diabetes mellitus as an important factor when deciding on a revascularization strategy, particularly when complex or extensive CAD is present (Figure 2).

See Online Data Supplements 21 and 22 for additional data regarding diabetes mellitus.

3.9.2. Chronic Kidney Disease

Cardiovascular morbidity and mortality rates are markedly increased in patients with chronic kidney disease (CKD) when compared with age-matched controls without CKD. The mortality rate for patients on hemodialysis is >20% per year, and approximately 50% of deaths among these patients are due to a cardiovascular cause (476,477).

To date, randomized comparisons of coronary revascularization (with CABG or PCI) and medical therapy in patients with CKD have not been reported. Some, but not all, observational studies or subgroup analyses have demonstrated an improved survival rate with revascularization compared with medical therapy in patients with CKD and multivessel CAD (478–480), despite the fact that the incidence of periprocedural complications (e.g., death, MI, stroke, infection, renal failure) is increased in patients with CKD compared with those without renal dysfunction. Some studies have shown that CABG is associated with a greater survival benefit than PCI among patients with severe renal dysfunction (479–485).

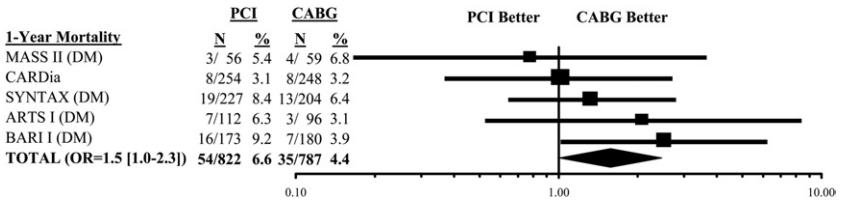

Figure 2. 1-Year Mortality After Revascularization for Multivessel Disease and Diabetes Mellitus

An OR of >1 suggests an advantage of CABG over PCI. ARTS I indicates Arterial Revascularization Therapy Study I (474); BARI I, Bypass Angioplasty Revascularization Investigation I (362); CARDia, Coronary Artery Revascularization in Diabetes (475); CI, confidence interval; DM, diabetes mellitus; MASS II, Medicine, Angioplasty, or Surgery Study II (366); OR, odds ratio; SYNTAX, Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery; and W, weighted (364).

ARTICLE IN PRESS

3.9.3. Completeness of Revascularization

Most patients undergoing CABG receive complete or nearly complete revascularization, which seems to influence long-term prognosis positively (486). In contrast, complete revascularization is accomplished less often in subjects receiving PCI (e.g., in <70% of patients), but the extent to which the absence of complete initial revascularization influences outcome is less clear. Rates of late survival and survival free of MI appear to be similar in patients with and without complete revascularization after PCI. Nevertheless, the need for subsequent CABG is usually higher in those whose initial revascularization procedure was incomplete (compared with those with complete revascularization) after PCI (487–489).

3.9.4. LV Systolic Dysfunction

Several older studies and a meta-analysis of the data from these studies reported that patients with LV systolic dysfunction (predominantly mild to moderate in severity) had better survival with CABG than with medical therapy alone (318,352–356). For patients with more severe LV systolic dysfunction, however, the evidence that CABG results in better survival compared with medical therapy is lacking. In the STICH (Surgical Treatment for Ischemic Heart Failure) trial of subjects with LVEF <35% with or without viability testing, CABG and GDMT resulted in similar rates of survival (death from any cause, the study's primary outcome) after 5 years of follow-up. For a number of secondary outcomes at this time point, including 1) death from any cause or hospitalization for heart failure, 2) death from any cause or hospitalization for cardiovascular causes, 3) death from any cause or hospitalization for any cause, or 4) death from any cause or revascularization with PCI or CABG, CABG was superior to GDMT. Although the primary outcome (death from any cause) was similar in the 2 treatment groups after an average of 5 years of follow-up, the data suggest the possibility that outcomes would differ if the follow-up were longer in duration; as a result, the study is being continued to provide follow-up for up to 10 years (371,372).

Only very limited data comparing PCI with medical therapy in patients with LV systolic dysfunction are available (356). In several ways, these data are suboptimal, in that many studies compared CABG with balloon angioplasty, many were retrospective, and many were based on cohort or registry data. Some of the studies demonstrated a similar survival rate in patients having CABG and PCI (359,451,490–492), whereas others showed that those undergoing CABG had better outcomes (320). The data that exist at present on revascularization in patients with CAD and LV systolic dysfunction are more robust for CABG than for PCI, although data from contemporary RCTs in this patient population are lacking. Therefore, the choice of revascularization in patients with CAD and LV systolic dysfunction is best based on clinical variables (e.g., coronary anatomy, presence of diabetes mellitus, presence of CKD), magnitude of LV systolic dysfunction, patient preferences, clinical judgment, and consultation between the interventional cardiologist and the cardiac surgeon.

3.9.5. Previous CABG

In patients with recurrent angina after CABG, repeat revascularization is most likely to improve survival in subjects at highest risk, such as those with obstruction of the proximal LAD artery and extensive anterior ischemia (373–381). Patients with ischemia in other locations and those with a patent LIMA to the LAD artery are unlikely to experience a survival benefit from repeat revascularization (380).

Cohort studies comparing PCI and CABG among post-CABG patients report similar rates of mid- and long-term survival after the 2 procedures (373,376–379,381,493). In the patient with previous CABG who is referred for revascularization for medically refractory ischemia, factors that may support the choice of repeat CABG include vessels unsuitable for PCI, number of diseased bypass grafts, availability of the IMA for grafting, chronically occluded coronary arteries, and good distal targets for bypass graft placement. Factors favoring PCI over CABG include limited areas of ischemia causing symptoms, suitable PCI targets, a patent graft to the LAD artery, poor CABG targets, and comorbid conditions.

3.9.6. Unstable Angina/Non–ST-Elevation Myocardial Infarction

The main difference between management of the patient with SIHD and the patient with UA/NSTEMI is that the impetus for revascularization is stronger in the setting of UA/NSTEMI, because myocardial ischemia occurring as part of an ACS is potentially life threatening, and associated anginal symptoms are more likely to be reduced with a revascularization procedure than with GDMT (494–496). Thus, the indications for revascularization are strengthened by the acuity of presentation, the extent of ischemia, and the ability to achieve full revascularization. The choice of revascularization method is generally dictated by the same considerations used to decide on PCI or CABG for patients with SIHD.

3.9.7. DAPT Compliance and Stent Thrombosis: Recommendation

CLASS III: HARM

1. **PCI with coronary stenting (BMS or DES) should not be performed if the patient is not likely to be able to tolerate and comply with DAPT for the appropriate duration of treatment based on the type of stent implanted (497–500). *(Level of Evidence: B)***

The risk of stent thrombosis is increased dramatically in patients who prematurely discontinue DAPT, and stent thrombosis is associated with a mortality rate of 20% to 45% (497). Because the risk of stent thrombosis with BMS is greatest in the first 14 to 30 days, this is the generally

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

recommended minimum duration of DAPT therapy for these individuals. Consensus in clinical practice is to treat DES patients for at least 12 months with DAPT to avoid late (after 30 days) stent thrombosis (497,501). Therefore, the ability of the patient to tolerate and comply with at least 30 days of DAPT with BMS treatment and at least 12 months of DAPT with DES treatment is an important consideration in deciding whether to use PCI to treat patients with CAD.

3.10. TMR as an Adjunct to CABG

TMR has been used on occasion in patients with severe angina refractory to GDMT in whom complete revascularization cannot be achieved with PCI and/or CABG. Although the mechanism by which TMR might be efficacious in these patients is unknown (502,503), several RCTs of TMR as sole therapy demonstrated a reduction in anginal symptoms compared with intensive medical therapy alone (397–399,504–506). A single randomized multicenter comparison of TMR (with a holmium:YAG laser) plus CABG and CABG alone in subjects in whom some myocardial segments were perfused by arteries considered not amenable to grafting showed a significant reduction in perioperative mortality rate (1.5% versus 7.6%, respectively), and the survival benefit of the TMR–CABG combination was present after 1 year of follow-up (400). At the same time, a large retrospective analysis of data from the STS National Cardiac Database, as well as a study of 169 patients from the Washington Hospital Center who underwent combined TMR–CABG, showed no difference in adjusted mortality rate compared with CABG alone (401,507). In short, a TMR–CABG combination does not appear to improve survival compared with CABG alone. In selected patients, however, such a combination may be superior to CABG alone in relieving angina.

3.11. Hybrid Coronary Revascularization: Recommendations

CLASS IIa

1. Hybrid coronary revascularization (defined as the planned combination of LIMA-to-LAD artery grafting and PCI of ≥1 non-LAD coronary arteries) is reasonable in patients with 1 or more of the following (508–516) *(Level of Evidence: B)*:
   a. Limitations to traditional CABG, such as heavily calcified proximal aorta or poor target vessels for CABG (but amenable to PCI);
   b. Lack of suitable graft conduits;
   c. Unfavorable LAD artery for PCI (i.e., excessive vessel tortuosity or chronic total occlusion).

CLASS IIb

1. Hybrid coronary revascularization (defined as the planned combination of LIMA-to-LAD artery grafting and PCI of ≥1 non-LAD coronary arteries) may be reasonable as an alternative to multivessel PCI or CABG in an attempt to improve the overall risk–benefit ratio of the procedures. *(Level of Evidence: C)*

Hybrid coronary revascularization, defined as the planned combination of LIMA-to-LAD artery grafting and PCI of ≥1 non-LAD coronary arteries (515), is intended to combine the advantages of CABG (i.e., durability of the LIMA graft) and PCI (516). Patients with multivessel CAD (e.g., LAD and ≥1 non-LAD stenoses) and an indication for revascularization are potentially eligible for this approach. Hybrid revascularization is ideal in patients in whom technical or anatomic limitations to CABG or PCI alone may be present and for whom minimizing the invasiveness (and therefore the risk of morbidity and mortality) of surgical intervention is preferred (510) (e.g., patients with severe preexisting comorbidities, recent MI, a lack of suitable graft conduits, a heavily calcified ascending aorta, or a non-LAD coronary artery unsuitable for bypass but amenable to PCI, and situations in which PCI of the LAD artery is not feasible because of excessive tortuosity or chronic total occlusion).

Hybrid coronary revascularization may be performed in a hybrid suite in one operative setting or as a staged procedure (i.e., PCI and CABG performed in 2 different operative suites, separated by hours to 2 days, but typically during the same hospital stay). Because most hospitals lack a hybrid operating room, staged procedures are usually performed. With the staged procedure, CABG before PCI is preferred, because this approach allows the interventional cardiologist to 1) verify the patency of the LIMA-to-LAD artery graft before attempting PCI of other vessels and 2) minimize the risk of perioperative bleeding that would occur if CABG were performed after PCI (i.e., while the patient is receiving DAPT). Because minimally invasive CABG may be associated with lower graft patency rates compared with CABG performed through a midline sternotomy, it seems prudent to angiographically image all grafts performed through a minimally invasive approach to confirm graft patency (510).

To date, no RCTs involving hybrid coronary revascularization have been published. Over the past 10 years, several small, retrospective series of hybrid revascularization using minimally invasive CABG and PCI have reported low mortality rates (0 to 2%) and event-free survival rates of 83% to 92% at 6 to 12 months of follow-up. The few series that have compared the outcomes of hybrid coronary revascularization with standard CABG report similar outcomes at 30 days and 6 months (508–514).

4. Perioperative Management

4.1. Preoperative Antiplatelet Therapy: Recommendations

CLASS I

1. Aspirin (100 mg to 325 mg daily) should be administered to CABG patients preoperatively (517–519). *(Level of Evidence: B)*
2. In patients referred for elective CABG, clopidogrel and ticagrelor should be discontinued for at least 5 days before surgery (520–522) *(Level of Evidence: B)* and prasugrel for at least 7 days *(Level of Evidence: C)* to limit blood transfusions.
3. In patients referred for urgent CABG, clopidogrel and ticagrelor should be discontinued for at least 24 hours to reduce major bleeding complications (521,523–525). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

4. In patients referred for CABG, short-acting intravenous glycoprotein IIb/IIIa inhibitors (eptifibatide or tirofiban) should be discontinued for at least 2 to 4 hours before surgery (526,527) and abciximab for at least 12 hours beforehand (528) to limit blood loss and transfusions. *(Level of Evidence: B)*

CLASS IIb

1. In patients referred for urgent CABG, it may be reasonable to perform surgery less than 5 days after clopidogrel or ticagrelor has been discontinued and less than 7 days after prasugrel has been discontinued. *(Level of Evidence: C)*

Nearly all patients with UA or recent MI in whom CABG is performed will be taking aspirin; CABG can be performed safely in these individuals, with only a modest increase in bleeding risk. Preoperative aspirin use reduces operative morbidity and mortality rates (517,518).

Although the use of thienopyridines (clopidogrel or prasugrel) is associated with improved outcomes in subjects with UA or NSTEMI (305,306), their use is associated with an increase in post-CABG bleeding and need for transfusions (520,522,529–533). The risk of major bleeding complications (i.e., pericardial tamponade or reoperation) is increased when CABG is performed <24 hours after clopidogrel's discontinuation (524,525). Conversely, no increase in bleeding or transfusions is noted when CABG is performed >5 days after clopidogrel has been stopped (529,532). The magnitude of bleeding risk when CABG is performed 1 to 4 days after the discontinuation of clopidogrel is less certain. Although the incidence of life-threatening bleeding does not appear to be significantly increased during this time, an increase in blood transfusions is likely (523,524,529,531). Accordingly, from the perspective of blood conservation, it is reasonable to delay elective CABG for ≥5 days after discontinuing clopidogrel. For patients requiring more urgent CABG, it can be performed >24 hours after clopidogrel has been stopped with little or no increased risk of major bleeding. Approximately two thirds of clopidogrel-treated patients undergo CABG <5 days after clopidogrel discontinuation (529,532), driven largely by concerns for patient stability, resource utilization, patient preference, and the confidence of the surgical team in managing hemostasis. Little experience with CABG in patients treated with prasugrel has been reported. In the TRITON-TIMI 38 (Trial to Assess Improvement in Therapeutic Outcomes by Optimizing Platelet Inhibition With Prasugrel Thrombolysis in Myocardial Infarction) trial, the incidence of CABG-related major bleeding was higher in prasugrel-treated patients than in those on clopidogrel (13.4% versus 3.2%; $p<0.001$) (533). When possible, therefore, CABG should be delayed for ≥7 days after prasugrel is discontinued (533).

Ticagrelor, an oral agent that binds reversibly to the platelet $P2Y_{12}$ receptor, provides faster, more effective, and more consistent inhibition of platelet aggregation and more rapid recovery of platelet function after discontinuation than clopidogrel (534). In the PLATO (Platelet Inhibition and Patient Outcomes) trial, 632 patients in the ticagrelor group and 629 in the clopidogrel group underwent CABG within 7 days of the last dose of study drug (521). Although the study protocol recommended waiting ≥5 days after stopping clopidogrel and 24 to 72 hours after ticagrelor, many patients underwent surgery before the recommended waiting times. The rates of major bleeding (59.3% with ticagrelor, 57.6% with clopidogrel) and transfusion requirements (55.7% with ticagrelor, 56.5% with clopidogrel) were similar. Furthermore, no difference in bleeding was noted between ticagrelor and clopidogrel with respect to time from last dose of study drug, even when CABG was performed 1, 2, or 3 days after discontinuation. On the basis of these data, it does not appear that the more rapid recovery of platelet function seen in ticagrelor pharmacokinetic studies translates to a lower risk of bleeding or less need for transfusion compared with clopidogrel when CABG is performed early (i.e., <5 days) after drug discontinuation.

4.2. Postoperative Antiplatelet Therapy: Recommendations

CLASS I

1. If aspirin (100 mg to 325 mg daily) was not initiated preoperatively, it should be initiated within 6 hours postoperatively and then continued indefinitely to reduce the occurrence of SVG closure and adverse cardiovascular events (519,535,536). *(Level of Evidence: A)*

CLASS IIa

1. For patients undergoing CABG, clopidogrel 75 mg daily is a reasonable alternative in patients who are intolerant of or allergic to aspirin. *(Level of Evidence: C)*

See Online Data Supplement 23 for additional data on postoperative antiplatelet therapy.

Aspirin significantly improves SVG patency rates, particularly during the first postoperative year. Because arterial graft patency rates are high even in the absence of antiplatelet therapy, the administration of such therapy has not shown an improvement. Aspirin administration before CABG offers no improvement in subsequent SVG patency compared with its early postoperative initiation (535). Prospective controlled trials have demonstrated a graft patency benefit when aspirin was started 1, 7, or 24 hours after operation (103,537); in contrast, the benefit of postoperative aspirin on SVG patency was lost when it was initiated >48 hours after surgery (538).

Dosing regimens ranging from 100 mg daily to 325 mg 3 times daily appear to be efficacious (539). As the grafted recipient's coronary arterial luminal diameter increases, SVG patency rates improve, and the relative advantage of aspirin over placebo is reduced (540). Although aspirin doses of <100 mg daily have been used for prevention of adverse events in patients with CAD, they may be less efficacious than higher doses in optimizing SVG patency (541). Enteric-coated aspirin, 75 mg, has been associated with suboptimal inhibition of platelet aggregation in 44% of patients with stable cardiovascular disease, suggesting that soluble aspirin may be preferred if low-dose aspirin is used

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

(542). When given within 48 hours after CABG, aspirin has been shown to reduce subsequent rates of mortality, MI, stroke, renal failure, and bowel infarction (519).

Although ticlopidine is efficacious at inhibiting platelet aggregation, it offers no advantage over aspirin except as an alternative in the truly aspirin-allergic patient (543). In addition, its use may be associated with potentially life-threatening neutropenia, a rare adverse effect, such that white blood cell counts should be monitored repetitively after initiating it. Dipyridamole and warfarin add nothing to the effect of aspirin on SVG patency (544,545), and use of the latter may be associated with an increased risk for bleeding compared with antiplatelet agents (546).

Clopidogrel is associated with fewer adverse effects than ticlopidine. Severe leukopenia occurs very rarely (546,547). A subset analysis of CABG patients from the CURE (Clopidogrel in Unstable Angina to Prevent Recurrent Ischemic Events) trial suggested that clopidogrel reduced the occurrence of cardiovascular death, MI, and stroke (14.5%) compared with placebo (16.2%). This benefit occurred primarily before surgery, however, and after CABG a difference in primary endpoints between groups was not demonstrable. Clopidogrel was stopped a median of 10 days before surgery and was restarted postoperatively in 75.3% of patients assigned to receive it. All patients received aspirin, 75 mg to 325 mg daily, but the details of aspirin administration in the study groups were not described (530).

4.3. Management of Hyperlipidemia: Recommendations

CLASS I

1. All patients undergoing CABG should receive statin therapy, unless contraindicated (545,548–559). *(Level of Evidence: A)*
2. In patients undergoing CABG, an adequate dose of statin should be used to reduce LDL cholesterol to less than 100 mg/dL and to achieve at least a 30% lowering of LDL cholesterol (548–552). *(Level of Evidence: C)*

CLASS IIa

1. In patients undergoing CABG, it is reasonable to treat with statin therapy to lower the LDL cholesterol to less than 70 mg/dL in very high-risk* patients (549–551,561–563). *(Level of Evidence: C)*
2. For patients undergoing urgent or emergency CABG who are not taking a statin, it is reasonable to initiate high-dose statin therapy immediately (564). *(Level of Evidence: C)*

CLASS III: HARM

1. Discontinuation of statin or other dyslipidemic therapy is not recommended before or after CABG in patients without adverse reactions to therapy (565–567). *(Level of Evidence: B)*

See Online Data Supplement 24 for additional data on management of hyperlipidemia.

*Presence of established cardiovascular disease plus 1) multiple major risk factors (especially diabetes), 2) severe and poorly controlled risk factors (especially continued cigarette smoking), 3) multiple risk factors of the metabolic syndrome (especially high triglycerides ≥200 mg/dL plus non–high-density lipoprotein cholesterol ≥130 mg/dL with low high-density lipoprotein cholesterol [<40 mg/dL]), and 4) acute coronary syndromes.

In patients with CAD, treatment of hyperlipidemia with therapeutic lifestyle changes and medications reduces the risk of nonfatal MI and death. The goal of such therapy is to reduce the LDL cholesterol level to <100 mg/dL (563). Statins are the most commonly prescribed agents for achieving this goal (563).

Studies of lipid-lowering therapy in CABG patients have demonstrated that lowering LDL cholesterol with statins influences post-CABG outcomes, and "aggressive" LDL cholesterol lowering (to 60 to 85 mg/dL) is associated with a reduced rate of graft atherosclerosis and repeat revascularization compared with only "moderate" lowering (130 to 140 mg/dL) (545,556). In the latter study, both groups of subjects initially received lovastatin at different doses (40 mg in the "aggressive" lowering group versus 2.5 mg in the "moderate" group), and cholestyramine was added if LDL cholesterol goals were not met with lovastatin alone. Of note, patients were maintained on therapy for ≥1 year, and as many as 11 years, after CABG.

The PROVE IT TIMI-22 (Pravastatin or Atorvastatin Evaluation and Infection Therapy: Thrombolysis in Myocardial Infarction) trial randomly assigned patients with ACS, a minority of whom had previous CABG, to intensive (LDL cholesterol goal <70 mg/dL) versus standard (LDL cholesterol goal <100 mg/dL) lipid-lowering therapy. The benefit of intensive therapy (a reduction in death, MI, recurrent UA, repeat revascularization, or stroke) was observed within 30 days (561). In the occasional subject who cannot take statins, alternative hypolipidemic agents, such as bile acid sequestrants, niacin, and fibrates, should be considered, in accordance with National Cholesterol Education Program: Adult Treatment Panel III guidelines (563).

4.3.1. Timing of Statin Use and CABG Outcomes

As noted, the benefits of post-CABG LDL lowering with statins have been reported previously, but no prospective studies of the impact of preoperative LDL cholesterol lowering on post-CABG outcomes are available. One small randomized comparison of preoperative placebo and a statin (initiated 1 week before CABG) showed a reduction in elevated perioperative cardiac biomarkers with statin therapy (554). Several nonrandomized, retrospective studies have noted an association between preoperative statin use and reduced rates of postoperative nonfatal MI and death (553,555,557–559). In addition, preoperative statin use has been associated with reduced rates of postoperative atrial fibrillation (AF) (571,572), neurological dysfunction (555, 573,574), renal dysfunction (575), and infection (576). Untreated hyperlipidemic patients have been shown to have a higher risk of post-CABG events than that of treated hyperlipidemic patients and those with normal serum lipid concentrations (567). In patients undergoing CABG who are not on statin therapy or at LDL goal, it seems reasonable to initiate intensive statin therapy preoperatively (i.e., no later than 1 week before surgery).

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Postoperatively, statin use should be resumed when the patient is able to take oral medications and should be continued indefinitely. Patients in whom statins were discontinued after CABG have been shown to have a higher mortality rate than those in whom statins were continued postoperatively (566).

4.3.1.1. POTENTIAL ADVERSE EFFECTS OF PERIOPERATIVE STATIN THERAPY

The most common adverse effects reported with statin use are myopathy and hepatotoxicity. Muscle aches have been reported in about 5% of patients treated with statins, although several pooled analyses of RCTs have shown a similar rate of muscle aches with placebo (577). Myositis, defined as muscle pain with a serum creatine kinase >10 times the upper limit of normal, occurs in 0.1% to 0.2% of statin users, and rhabdomyolysis occurs in 0.02% (578,579). In addition, approximately 2% of patients are observed to have elevated liver enzymes (i.e., alanine and aspartate transaminases) in the weeks to months after statin initiation, but no data are available to suggest that these elevations are associated with permanent hepatotoxicity or an increased risk of hepatitis. Nonetheless, the presence of active or chronic liver disease is a contraindication to statin use, and patients initiated on a statin should be monitored for the development of myositis or rhabdomyolosis, either of which would mandate its discontinuation (580).

4.4. Hormonal Manipulation: Recommendations

CLASS I

1. Use of continuous intravenous insulin to achieve and maintain an early postoperative blood glucose concentration less than or equal to 180 mg/dL while avoiding hypoglycemia is indicated to reduce the incidence of adverse events, including deep sternal wound infection, after CABG (581–583). *(Level of Evidence: B)*

CLASS IIb

1. The use of continuous intravenous insulin designed to achieve a target intraoperative blood glucose concentration less than 140 mg/dL has uncertain effectiveness (584–586). *(Level of Evidence: B)*

CLASS III: HARM

1. Postmenopausal hormonal therapy (estrogen/progesterone) should not be administered to women undergoing CABG (587–589). *(Level of Evidence: B)*

4.4.1. Glucose Control

Hyperglycemia often occurs during and after CABG, particularly when CABG is performed on pump. Intraoperative hyperglycemia is associated with an increased morbidity rate in patients with diabetes (590) and with excess mortality in patients with and without diabetes (591). Hyperglycemia during CPB is an independent risk factor for death in patients undergoing cardiac surgery. A retrospective observational study of 409 cardiac surgical patients identified intraoperative hyperglycemia as an independent risk factor for perioperative complications, including death, and calculated a 34% increased likelihood of postoperative complications for every 20-mg/dL increase in blood glucose concentration >100 mg/dL during surgery (592). An RCT of critically ill patients, many of whom had high-risk cardiac surgery, found reduced morbidity and mortality rates in those whose blood glucose was tightly controlled (583), and follow-up of these subjects showed that this benefit persisted for up to 4 years (582).

The Portland Diabetes Project, begun in 1992, was the first large study to elucidate the detrimental effects of hyperglycemia in relation to CABG outcomes. This prospective observational study described the evolution in management of cardiac surgical patients with diabetes mellitus from a strategy of intermittent subcutaneous injections of insulin to one of continuous intravenous insulin infusion with decreasing target glucose concentrations. As this management strategy evolved, the upper target serum glucose concentrations declined from 200 mg/dL to 110 mg/dL, with which significant reductions in operative and cardiac-related death (arrhythmias and acute ventricular failure) were noted (581). In addition, continuous intravenous insulin to maintain a serum glucose concentration of 120 mg/dL to 160 mg/dL resulted in a reduced incidence of deep sternal wound infection (593,594). As a result, most centers now emphasize tight glucose control (target serum glucose concentration ≤180 mg/dL, accomplished with a continuous intravenous insulin infusion) during surgery and until the morning of the third postoperative day.

Whether extremely tight intraoperative glucose control can further reduce morbidity or mortality rate is controversial. A prospective trial from the Mayo Clinic randomly assigned 400 patients to intensive treatment (continuous insulin infusion during surgery) or conventional treatment (insulin given only for a glucose concentration >200 mg/dL) (586). Postoperative ICU management was similar in the 2 groups. Although no difference was noted between groups in a composite endpoint of death, deep sternal wound infection, prolonged ventilation, cardiac arrhythmias, stroke, or renal failure within 30 days of surgery, intensive treatment caused an increased incidence of death and stroke, thereby raising concerns about this intervention (586). In a prospective RCT in 381 CABG patients without diabetes, those with an intraoperative blood glucose concentration >100 mg/dL were assigned to an insulin infusion or no treatment (584). Those receiving insulin had lower intraoperative glucose concentrations, but no difference between groups was observed in the occurrence of new neurological, neuro-ophthalmologic, or neurobehavioral deficits or neurology-related deaths. Of note, no difference in need for inotropic support, hospital length of stay, or operative mortality rate was seen between the groups (584). A retrospective analysis of intraoperative and postoperative ICU glucose concentrations in >4,300 patients undergoing cardiac surgery at the Cleveland Clinic observed that a blood glucose concentration >200 mg/dL in the operating room or ICU was associated with worse outcomes, but intraoperative glucose concentrations ≤140 mg/dL were not associated with improved outcomes compared with severe

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

hyperglycemia, despite infrequent hypoglycemia. Diabetic status did not influence the effects of hyperglycemia (585). In short, until additional information is available, extremely tight intraoperative glucose control is not recommended.

Although the management of blood glucose before surgery in patients with and without diabetes mellitus is not well studied, an increased incidence of adverse outcomes has been noted in patients with poor preoperative glycemic control (593,595). As a result, most centers now attempt to optimize glucose control before surgery, attempting to achieve a target glucose concentration ≤180 mg/dL with continuous intravenous insulin. Measuring preoperative hemoglobin A1c concentrations may be helpful in assessing the adequacy of preoperative glycemic control and identifying patients at risk for postoperative hyperglycemia (596).

4.4.2. Postmenopausal Hormone Therapy

Postmenopausal hormone therapy was shown previously to reduce the risk of cardiac-related death. However, more contemporary published RCTs have suggested that it may have adverse cardiovascular effects. The Women's Health Initiative randomly assigned >16,000 healthy postmenopausal women to placebo or continuous combined estrogen–progestin therapy. Hormone therapy was discontinued early because of an increased risk of breast cancer in those receiving it. Additionally, subjects receiving it had an increased incidence of cardiac ischemic events (29% increase, mainly nonfatal MI), stroke, and venous thromboembolism (588). A secondary prevention trial, HERS (Heart and Estrogen/Progestin Replacement Study), randomly assigned 2,763 postmenopausal women with known CAD to continuous estrogen/progestin or placebo, after which they were followed up for a mean of 4.1 years (587). No difference in the primary endpoints of nonfatal MI and CAD death was noted, but those receiving hormone therapy had a greater incidence of deep venous thrombosis and other thromboembolic events. This predisposition to thrombosis has raised concerns that hormone therapy may cause adverse events at the time of CABG. A prospective RCT comparing hormone therapy to placebo in postmenopausal women after CABG was initiated in 1998 but was stopped when the Women's Health Initiative trial results were reported (589). Eighty-three subjects were enrolled, and 45 underwent angiographic follow-up at 42 months. Angiographic progression of CAD in nonbypassed coronary arteries was greater in patients receiving hormone therapy, although less progression of disease was observed in SVGs. Postoperative angioplasty was performed in 8 hormone therapy patients and only 1 placebo subject ($p<0.05$). On the basis of these data, it is not recommended that postmenopausal hormone therapy be initiated in women undergoing CABG, and it may be reasonable to discontinue it in those scheduled for elective CABG.

4.4.3. CABG in Patients With Hypothyroidism

Subclinical hypothyroidism (thyroid-stimulating hormone concentration, 4.50 mIU/L to 19.9 mIU/L) occurs commonly in patients with CAD. In a meta-analysis of >55,000 subjects with CAD, those with subclinical hypothyroidism did not have an increase in total deaths, but the CAD mortality rate was increased, particularly in those with thyroid-stimulating hormone concentrations >10 mIU/L (597).

The risks of CABG in hypothyroid patients are poorly defined. A retrospective study of hypothyroid patients undergoing CABG had a higher incidence of heart failure and gastrointestinal complications and a lower incidence of postoperative fever than did members of a matched euthyroid group (598). Patients with subclinical hypothyroidism may be at increased risk for developing AF after CABG (599), and 1 study even suggested that triiodothyronine supplementation in patients undergoing CABG (including those who are euthyroid) decreased the incidence of postoperative AF (600). Conversely, controlled studies of triiodothyronine in subjects undergoing CABG have shown no benefit (601,602). Rarely, patients may develop severe hypothyroidism after CABG, which manifests as lethargy, prolonged required ventilation, and hypotension (603). Thyroid replacement is indicated in these individuals.

4.5. Perioperative Beta Blockers: Recommendations

CLASS I

1. Beta blockers should be administered for at least 24 hours before CABG to all patients without contraindications to reduce the incidence or clinical sequelae of postoperative AF (604–608,608a–608c). *(Level of Evidence: B)*
2. Beta blockers should be reinstituted as soon as possible after CABG in all patients without contraindications to reduce the incidence or clinical sequelae of AF (604–608,608a–608c). *(Level of Evidence: B)*
3. Beta blockers should be prescribed to all CABG patients without contraindications at the time of hospital discharge. *(Level of Evidence: C)*

CLASS IIa

1. Preoperative use of beta blockers in patients without contraindications, particularly in those with an LVEF greater than 30%, can be effective in reducing the risk of in-hospital mortality (609–611). *(Level of Evidence: B)*
2. Beta blockers can be effective in reducing the incidence of perioperative myocardial ischemia (612–615). *(Level of Evidence: B)*
3. Intravenous administration of beta blockers in clinically stable patients unable to take oral medications is reasonable in the early postoperative period (616). *(Level of Evidence: B)*

CLASS IIb

1. The effectiveness of preoperative beta blockers in reducing in-hospital mortality rate in patients with LVEF less than 30% is uncertain (609,617). *(Level of Evidence: B)*

See Online Data Supplement 25 for additional data on beta blockers.

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

Because beta blockers have been shown to reduce the incidence of postoperative AF in CABG patients who are receiving them preoperatively (604,605,608) (Section 5.2.5), the STS and AHA recommend that they be administered preoperatively to all patients without contraindications and then be continued postoperatively (618,619). Despite this recommendation, uncertainty exists about their efficacy in subjects not receiving them preoperatively; in this patient population, their use appears to lengthen hospital stay and not to reduce the incidence of postoperative AF (604,607). Their efficacy in preventing or treating perioperative myocardial ischemia is supported by the results of observational studies and small RCTs (612–614). Although a meta-analysis of available data did not show an improvement in outcomes with perioperative beta blockers (615), observational analyses suggest that preoperative beta-blocker use is associated with a reduction in perioperative deaths (609–611). Another analysis of data from 629,877 patients reported a mortality rate of 2.8% in those receiving beta blockers versus 3.4% in those not receiving them (609).

Few data are available on the pharmacokinetic disposition of beta blockers in the early postoperative period, when an alteration in gastrointestinal perfusion may adversely affect their absorption after oral administration. An RCT demonstrated a significant reduction in the incidence of postoperative AF when a continuous intravenous infusion of metoprolol was used rather than oral administration (616).

The efficacy of beta-blocker use in CABG patients after hospital discharge is uncertain, as data from 2 RCTs and 1 large detailed observational analysis suggest that they exert no benefit over 2 years postoperatively (621–623). In contrast, some observational analyses have reported that they are, in fact, efficacious in high-risk subgroups (e.g., those with perioperative myocardial ischemia or elderly subjects with heart failure) (624). A contemporary analysis of prescription data from 3,102 Canadian patients, 83% of whom were prescribed a beta blocker at the time of discharge, reported that those receiving beta blockers had a reduced mortality rate during a mean follow-up of 75 months (625). Of note, improved survival was noted in all patient subgroups receiving beta blockers, even including those without perioperative myocardial ischemia or heart failure.

4.6. ACE Inhibitors/ARBs: Recommendations

CLASS I

1. ACE inhibitors and ARBs given before CABG should be reinstituted postoperatively once the patient is stable, unless contraindicated (622,626,627). *(Level of Evidence: B)*
2. ACE inhibitors or ARBs should be initiated postoperatively and continued indefinitely in CABG patients who were not receiving them preoperatively, who are stable, and who have an LVEF less than or equal to 40%, hypertension, diabetes mellitus, or CKD, unless contraindicated (622,627,627a,627b). *(Level of Evidence: A)*

CLASS IIa

1. It is reasonable to initiate ACE inhibitors or ARBs postoperatively and to continue them indefinitely in all CABG patients who were not receiving them preoperatively and are considered to be at low risk (i.e., those with a normal LVEF in whom cardiovascular risk factors are well controlled), unless contraindicated (622,627–630). *(Level of Evidence: B)*

CLASS IIb

1. The safety of the preoperative administration of ACE inhibitors or ARBs in patients on chronic therapy is uncertain (631–636). *(Level of Evidence: B)*
2. The safety of initiating ACE inhibitors or ARBs before hospital discharge is not well established (622,628,630,640). *(Level of Evidence: B)*

See Online Data Supplements 26 and 27 for additional data on ACE inhibitors.

ACE inhibitors and ARBs are known to exert cardiovasculoprotective actions, particularly in subjects with LV systolic dysfunction, hypertension, diabetes mellitus, or chronic renal insufficiency (626). Nonetheless, the safety and effectiveness of preoperative ACE inhibitors and ARBs in patients undergoing cardiac or noncardiac surgery is uncertain (638) because their administration has been associated with intraoperative hypotension as well as a blunted response to pressors and inotropic agents after induction of anesthesia. Of particular concern during cardiac surgery is their reported association with severe hypotension after CPB (so-called vasoplegia syndrome) and postoperative renal dysfunction (631,639).

Although it has been postulated that these agents may protect against the development of postoperative AF, published studies have reached conflicting conclusions in this regard (634,636). The safety and efficacy of ACE inhibitors and ARBs after CABG in previously naïve low- to moderate-risk patients (i.e., subjects without diabetes mellitus or renal insufficiency and with or without asymptomatic moderate LV systolic dysfunction) are uncertain; furthermore, ACE inhibitors and ARBs must be used with caution in these subjects. They should not be instituted in the immediate postoperative period if the systolic arterial pressure is <100 mm Hg or if the patient develops hypotension in the hospital after receiving them. The IMAGINE (Ischemia Management With Accupril Post Bypass Graft via Inhibition of Angiotensin Converting Enzyme) study failed to show a beneficial effect of postoperative ACE inhibitor therapy 3 years after CABG, instead noting an increase in adverse events, particularly recurrent angina in the first 3 months of therapy (630). A subanalysis of the data from patients enrolled in EUROPA (European Trial on the Reduction of Cardiac Events with Perindopril in Stable Coronary Artery Disease) with previous revascularization (CABG or PCI no sooner than 6 months before enrollment) suggested a primary and secondary prevention benefit over a 4.2-year follow-up period; however, an analysis of the data from almost 3,000 patients in the

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

PREVENT IV (PRoject of Ex-vivo Vein graft ENgineering via Transfection) trial, all of whom were taking either ACE inhibitors or ARBs at the time of hospital discharge, failed to demonstrate a significant reduction in death or MI after 2 years of follow-up in "ideal" candidates (based on ACCF/AHA/HRS guidelines) (HR: 0.87; 95% CI: 0.52 to 1.45; p=NS), whereas significance was achieved in "non-ideal" candidates (HR: 1.64; 95% CI: 1.00 to 2.68; p=0.05) (608,622,628,640).

4.7. Smoking Cessation: Recommendations

CLASS I

1. All smokers should receive in-hospital educational counseling and be offered smoking cessation therapy during CABG hospitalization (642–644). *(Level of Evidence: A)*

CLASS IIb

1. The effectiveness of pharmacological therapy for smoking cessation offered to patients before hospital discharge is uncertain. *(Level of Evidence: C)*

See Online Data Supplement 28 for additional data on smoking cessation.

Smoking cessation after CABG is associated with a substantial reduction in subsequent MACE, including MI and death. Data from the randomized portion of the CASS study showed 10-year survival rates of 82% among the 468 patients who quit smoking after CABG and only 77% in the 312 who continued to smoke (p=0.025) (645). Those who continued to smoke were more likely to have recurrent angina and to require repeat hospitalization. Data from the CASS registry demonstrated 5-year mortality rates of 22% for those who continued to smoke and only 15% for those who successfully quit smoking after CABG (RR: 1.55; 95% CI: 1.29 to 1.85) (646). Similar favorable outcomes with smoking cessation were reported from the MRFIT (Multiple Risk Factor Intervention Trial), in which the impact of smoking cessation on MACE was assessed after 10.5 years of follow-up in 12,866 men; the risk of death was greater among smokers than nonsmokers (RR: 1.57) (647). Notably, the risk of dying from cardiac causes was lower for those who successfully quit than for nonquitters after only 1 year of smoking cessation (RR: 0.63), and it remained so in those who quit for at least the first 3 years of the study (RR: 0.38) (647). The beneficial effects of smoking cessation after CABG seem to be durable during long-term follow-up (i.e., even 30 years postoperatively) (648–650). In fact, smoking cessation was associated with a reduction in mortality rate of greater magnitude than that resulting from any other treatment or intervention after CABG (649). In these long-term follow-up studies, patients who continued to smoke had significantly higher rates of MI, reoperation, and death.

Smoking is a powerful independent predictor of sudden cardiac death in patients with CAD (HR: 2.47; 95% CI: 1.46 to 4.19). It has been associated with accelerated disease and occlusion of SVGs as well as endothelial dysfunction of arterial grafts (651–653). Compared with nonsmokers, subjects who are smoking at the time of CABG more often have pulmonary complications that require prolonged postoperative intubation and a longer ICU stay as well as postoperative infections (654–656). Even smokers who quit just before CABG have fewer postoperative complications than those who continued to smoke (654). As a result, all smokers referred for CABG should be counseled to quit smoking before surgery.

Smoking cessation seems to be especially beneficial for patients hospitalized with ACS who then require CABG (644,657). Independent predictors of continued nonsmoking 1 year after CABG included <3 previous attempts to quit (OR: 7.4; 95% CI: 1.9 to 29.1), >1 week of preoperative nonsmoking (OR: 10.0; 95% CI: 2.0 to 50), a definite intention to quit smoking (OR: 12.0; 95% CI: 2.6 to 55.1), and no difficulty with smoking cessation while in the hospital (OR: 9.6; 95% CI: 1.8 to 52.2) (658). Aggressive smoking cessation intervention directed at patients early after post-CABG discharge appears to be more effective than a conservative approach (642). In a systematic review of 33 trials of smoking cessation, counseling that began during hospitalization and included supportive contacts for >1 month after hospital discharge increased the rates of smoking cessation (OR: 1.65; 95% CI: 1.44 to 1.90), whereas the use of pharmacotherapy did not improve abstinence rates (643). These findings are supported by a 2009 RCT comparing intensive or minimal smoking cessation intervention in patients hospitalized for CABG or acute MI (644). In this trial, the 12-month self-reported rate of abstinence was 62% among patients randomly assigned to the intensive program and 46% among those randomly allocated to the minimal intervention (OR: 2.0; 95% CI: 1.2 to 3.1). Overall, a higher rate of continuous abstinence was observed in patients undergoing CABG than in those who had sustained an MI. Interestingly, the rates of abstinence were lower in subjects who used pharmacotherapy regardless of the intervention group (OR: 0.3; 95% CI: 0.2 to 0.5) (644).

Seven first-line pharmacological treatments are available for smoking cessation therapy, including 5 nicotine-replacement therapies; the antidepressant bupropion; and varenicline, a partial agonist of the $\alpha_4\beta_2$ subtype of the nicotinic acetylcholine receptor (659–661). The data supporting the use and timing of nicotine-replacement therapy after CABG are unclear. One study from a large general practice database reported no increased risk of MI, stroke, or death with nicotine-replacement therapy (662), whereas a retrospective case–control study of critically ill patients reported a higher in-hospital mortality rate in those receiving nicotine replacement (20% versus 7%; p=0.0085). Despite adjusting for the severity of illness, nicotine-replacement therapy was an independent predictor of in-hospital mortality (OR: 24.6; 95% CI: 3.6 to 167.6; p=0.0011) (663). Similarly, in a cohort study of post-CABG patients, nicotine-replacement therapy was shown

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

to be an independent predictor of in-hospital mortality after adjusting for baseline characteristics (OR: 6.06; 95% CI: 1.65 to 22.21) (663,664). Additional studies are needed to determine the safety of nicotine-replacement therapy in smokers undergoing CABG as well as the optimal time at which to begin such therapy postoperatively.

4.8. Emotional Dysfunction and Psychosocial Considerations: Recommendation

CLASS IIa

1. Cognitive behavior therapy or collaborative care for patients with clinical depression after CABG can be beneficial to reduce objective measures of depression (665–669). *(Level of Evidence: B)*

The negative impact of emotional dysfunction on risk of morbidity and mortality after CABG is well recognized. In a multivariate analysis of elderly patients after CABG, the 2 most important predictors of death were a lack of social participation and a lack of religious strength (670). Social isolation is associated with increased risk of death in patients with CAD (671), and treatment may improve outcomes (672). The most carefully studied mood disorder, depression, occurs commonly after CABG. Several studies have shown that the primary predictor of depression after CABG is its presence before CABG and that only rarely does CABG cause depression in patients who were not depressed beforehand. In 1 report, half the patients who were depressed before CABG were not depressed afterward, and only 9% of subjects who were not depressed before CABG developed depression postoperatively (673). The prevalence of depression at 1 year after CABG was 33%, which is similar to the prevalence in those undergoing other major operations. Patients with stronger perceptions of control of their illness were less likely to be depressed or anxious after CABG (674). No difference in the incidence of mood disturbances was noted when off-pump and on-pump CABG were compared (675).

4.8.1. Effects of Mood Disturbance and Anxiety on CABG Outcomes

Depression is an important risk factor for the development and progression of CAD. In fact, it is a more important predictor of the success of cardiac rehabilitation than many other functional cardiac variables (676). Both the presence of depressive symptoms before CABG and the postoperative worsening of these symptoms correlate with poorer physical and psychosocial functioning and poorer quality of life after CABG (677). In a study of 440 patients who underwent CABG, the effects of both preoperative anxiety and depression (as defined by the Depression Anxiety and Stress Scale) on mortality rate were assessed for a median of 5 years postoperatively (678). Interestingly, preoperative anxiety was associated with a significantly increased risk of death (HR: 1.88; 95% CI: 1.12 to 3.37; $p=0.02$), whereas preoperative depression was not (678). In a multivariate analysis of 817 patients at Duke University Medical Center, severe depression (assessed using the Center for Epidemiological Studies–Depression scale before surgery and 6 months postoperatively (665) was associated with increased risk of death (HR: 2.4; 95% CI: 1.4 to 4.0), as was mild or moderate depression that persisted at 6 months (HR: 2.2; 95% CI: 1.2 to 4.2). In another study of 309 subjects followed up for ≤1 year after CABG, those with diagnostic criteria for a major depressive disorder before discharge were nearly 3 times as likely to have a cardiac event, such as heart failure requiring hospitalization, MI, cardiac arrest, PCI, repeat CABG, or cardiac death (666). Finally, depression after CABG is an important predictor of the recurrence of angina during the first 5 postoperative years (666,673).

4.8.2. Interventions to Treat Depression in CABG Patients

The Bypassing the Blues investigators identified 302 patients who were depressed before CABG and 2 weeks after discharge (668). They were randomly assigned to 8 months of telephone-delivered collaborative care (150 patients) or "usual care" (152 patients). The 2 groups were compared with each other and also to another group of 151 randomly selected nondepressed post-CABG patients. At 8 month follow-up, the collaborative care group showed an improvement in quality of life and physical functioning and were more likely to report a >50% decline in the Hamilton Rating Score for Depression than the usual care group (50.0% versus 29.6%; $p<0.001$). Men were more likely to benefit from the intervention (668,669). In another study, 123 patients who met the Diagnostic and Statistical Manual of Mental Disorders, 4th edition, criteria for major or minor depression within 1 year of CABG were randomly assigned to 12 weeks of cognitive behavior therapy, 12 weeks of supportive stress management, or usual care (667). Both interventions were efficacious for treating depression after CABG, and cognitive behavior therapy had the most durable effects on depression and several secondary psychological outcome variables (667). Thus, both collaborative intervention and cognitive behavior therapy are effective for treating depression in patients after CABG. Given that depression is associated with adverse outcomes after CABG, it is likely that these interventions also may lead to reduced rates of morbidity and mortality.

4.9. Cardiac Rehabilitation: Recommendation

CLASS I

1. Cardiac rehabilitation is recommended for all eligible patients after CABG (679–681,681a–681d). *(Level of Evidence: A)*

See Online Data Supplement 29 for additional data on cardiac rehabilitation.

Cardiac rehabilitation, including early ambulation during hospitalization, outpatient prescriptive exercise training, and education, reduces risk of death in survivors of MI (682–684). Beginning 4 to 8 weeks after CABG, 3-times-weekly education and exercise sessions for 3 months are associated with a 35% increase in exercise tolerance

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

(p=0.0001), a slight (2%) (p=0.05) increase in high-density lipoprotein cholesterol, and a 6% reduction in body fat (p=0.002) (421). Exercise training is a valuable adjunct to dietary modification of fat and total caloric intake in maximizing the reduction of body fat while minimizing the reduction of lean body mass. Aerobic training improves volume of maximum oxygen consumption at 6 months compared with moderate continuous training (p<0.001) (685).

After hospital discharge, CABG patients were randomly assigned to standard care (n=109) or standard care plus rehabilitation (n=119). At 5 years, the groups were similar in symptoms, medication use, exercise capacity, and depression scores, but rehabilitated patients reported better physical mobility, better perceived health, and better perceived overall life situation. A larger proportion of the rehabilitated patients were working at 3 years, although this difference disappeared with longer follow-up (679). Subjects who sustained an MI followed by CABG had greater improvement in exercise tolerance after rehabilitation than did those who had an MI alone. Improvement was sustained for 2 years (686). Observational studies have reported that cardiac events are reduced with rehabilitation after revascularization (680).

In many CABG patients, initiation of rehabilitation is a substantial hurdle. Medically indigent patients seem to have rehabilitation compliance and benefit rates similar to those of insured or private-paying patients if rehabilitation is initiated promptly and is structured appropriately (687). In addition to contributing to a patient's sense of well-being, participation in cardiac rehabilitation offers an economic benefit. During a 3-year (mean: 21 months) follow-up after CABG or another coronary event, per capita hospitalization charges were $739 lower for rehabilitated patients compared with nonparticipants (688). Post-CABG patients are more likely to resume sexual activity than are survivors of MI. Anticipatory and proactive advice by the physician or surgeon on the safety of resumption of sexual activity as the patient reengages in other daily activities is beneficial (682).

Recommendations for intensive risk-reduction therapies for patients with established coronary and other atherosclerotic vascular disease are detailed in the "AHA/ACCF Secondary Prevention and Risk Reduction Therapy for Patients With Coronary and Other Atherosclerotic Vascular Disease: 2011 Update" (689). This updated guideline includes recommendations on smoking, blood pressure control, lipid management, physical therapy, weight management, type 2 diabetes management, antiplatelet agents and anticoagulants, renin–angiotensin–aldosterone system blockers (ACE inhibitors and ARBs), beta blockers, influenza vaccination, depression, and cardiac rehabilitation.

4.10. Perioperative Monitoring

4.10.1. Electrocardiographic Monitoring: Recommendations

CLASS I

1. Continuous monitoring of the electrocardiogram for arrhythmias should be performed for at least 48 hours in all patients after CABG (606,690,691). *(Level of Evidence: B)*

CLASS IIa

1. Continuous ST-segment monitoring for detection of ischemia is reasonable in the intraoperative period for patients undergoing CABG (53,692–694). *(Level of Evidence: B)*

CLASS IIb

1. Continuous ST-segment monitoring for detection of ischemia may be considered in the early postoperative period after CABG (613, 690,695–698). *(Level of Evidence: B)*

4.10.2. Pulmonary Artery Catheterization: Recommendations

CLASS I

1. Placement of a pulmonary artery catheter (PAC) is indicated, preferably before the induction of anesthesia or surgical incision, in patients in cardiogenic shock undergoing CABG. *(Level of Evidence: C)*

CLASS IIa

1. Placement of a PAC can be useful in the intraoperative or early postoperative period in patients with acute hemodynamic instability (699–704). *(Level of Evidence: B)*

CLASS IIb

1. Placement of a PAC may be reasonable in clinically stable patients undergoing CABG after consideration of baseline patient risk, the planned surgical procedure, and the practice setting (699–704). *(Level of Evidence: B)*

4.10.3. Central Nervous System Monitoring: Recommendations

CLASS IIb

1. The effectiveness of intraoperative monitoring of the processed electroencephalogram to reduce the possibility of adverse recall of clinical events or for detection of cerebral hypoperfusion in CABG patients is uncertain (705–707). *(Level of Evidence: B)*
2. The effectiveness of routine use of intraoperative or early postoperative monitoring of cerebral oxygen saturation via near-infrared spectroscopy to detect cerebral hypoperfusion in patients undergoing CABG is uncertain (708–710). *(Level of Evidence: B)*

See Online Data Supplement 30 for additional data on central nervous system monitoring.

Requirements for basic perioperative monitoring in patients undergoing CABG, including heart rate, blood pressure, peripheral oxygen saturation, and body temperature, are well accepted. Additional intraoperative standards established by the American Society of Anesthesiologists, including the addition of end-tidal carbon dioxide measurement in the intubated patient, are uniformly applied (711). Specialized monitoring of cardiac and cerebral function varies among centers and includes the use of PACs, TEE, or other forms of echocardiography (Section 2.1.7); noninvasive monitors of cardiac output; processed electroencephalographic monitoring; and cerebral oximetry with near-infrared spectroscopy. Given the added expense and potential hazards of such monitors (e.g., pulmonary artery rupture with PAC, false-positive changes with cerebral oximetry or processed electroencephalogram), substantial controversy exists about indications for their use. None of these monitoring methods is routinely recommended.

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Electrocardiographic monitoring includes an assessment of heart rate and rhythm as well as the morphology and deviation of the QRS complex and ST segments for evidence of ischemia, infarction, or abnormal conduction (690). Continuous telemetric monitoring of cardiac rate and rhythm is recommended for 48 to 72 hours after surgery in all patients because of the high incidence of post-CABG AF, which most often occurs 2 and 4 days after surgery (606,613,690,691,697,698). In addition, other arrhythmias and conduction abnormalities may occur in patients with ischemia because of incomplete revascularization or in those undergoing concurrent valve replacement.

Uncertainty continues with regard to the utility of PAC in low-risk patients undergoing CABG (712). Several observational studies suggest that such patients can be managed only with monitoring of central venous pressure, with insertion of a PAC held in reserve should the need arise. In fact, it has even been suggested that patients in whom a PAC is placed incur greater resource utilization and more aggressive therapy, which may lead to worse outcomes and higher costs. The reported rates of PAC use range from <10% in a combined private–academic setting to >90% in patients in the Department of Veterans Affairs health system (61,639,701,702,713).

Aside from providing an indirect assessment of left atrial pressure and the presence and severity of pulmonary hypertension, PAC can be used to measure cardiac output (by thermodilution) and to monitor the mixed venous oxygen saturation—information that may be helpful in the management of high-risk patients (712,714). The need for careful consideration of baseline patient risk, the planned procedure, and the patient setting before use of a PAC are outlined in several opinion pieces, consensus documents, the "Practice Guidelines for Pulmonary Artery Catheterization: An Updated Report by the American Society of Anesthesiologists", and the "2009 ACCF/AHA Focused Update on Perioperative Beta Blockade Incorporated Into the ACC/AHA 2007 Guidelines on Perioperative Cardiovascular Evaluation and Care for Noncardiac Surgery" (699,712,714–716). Pulmonary artery perforation or rupture is fatal in >50% of patients in whom it occurs. This complication usually can be avoided by 1) withdrawal of the catheter tip into the main pulmonary artery before initiation of CPB; 2) withdrawal of the catheter into the pulmonary artery before balloon inflation, especially if the pressure tracing suggests damping; and 3) avoiding routine measurement of the pulmonary artery wedge pressure, reserving this maneuver as a specific diagnostic event.

Perioperative monitoring of cerebral function (primarily with an electroencephalogram) has been used in certain high-risk patients, such as those undergoing neurosurgery or carotid vascular surgery (717). In the setting of cardiac surgery, the potentially deleterious effects of CPB on cerebral hypopfusion or embolic events (i.e., air or aortic calcific debris) have been investigated via transcranial Doppler techniques, with a lesser emphasis on the electroencephalogram (in part because of excessive artifact in this setting) (57,718). Although processed electroencephalographic monitors and bifrontal cerebral oximetry have been available for more than 2 decades, controversy remains about their clinical effectiveness (719,720). Processed electroencephalographic monitoring is aimed primarily at assessing the risk of conscious recall of intraoperative events, but it also has been used to gauge the depth of anesthesia, theoretically allowing more precise titration of the anesthetic (721,722). Although a variety of electroencephalographic variables are commonly accepted as markers of cerebral ischemia, the ability of current commercial devices to detect or quantify ischemia is limited (706,707,717,718).

Given the intuitive link between reflectance oximetry (i.e., for peripheral oxygen or mixed venous oxygen saturation) and clinical interventions (i.e., manipulating hemodynamic variables, the fraction of inspired oxygen, etc.), there is considerable interest in the use of bifrontal cerebral oximetry as a measure of brain perfusion (723). Two RCTs in CABG patients suggest that bifrontal cerebral oximetry may be helpful in predicting early perioperative cognitive decline, stroke, noncerebral complications, and ICU and hospital length of stay (709,710). A 2011 observational cohort (1,178 CABG patients) suggested that a patient's preoperative response to breathing oxygen for 2 minutes (Sco_2 ≤50%) is an independent predictor of death at 30 days and 1 year after surgery (724).

5. CABG-Associated Morbidity and Mortality: Occurrence and Prevention

Several comprehensive data registries for CABG have been developed in the United States, the largest being the STS Adult Cardiac Database. For >20 years, these registries have collected data on all aspects of the procedure (306,725,727). A detailed analysis of these data and their correlation to outcomes has facilitated the creation of risk-assessment models that estimate the rates at which various adverse events occur. On the basis of these models, risk-adjusted outcomes for hospitals and surgeons have been calculated and, in some instances, publicly reported.

5.1. Public Reporting of Cardiac Surgery Outcomes: Recommendation

CLASS I

1. Public reporting of cardiac surgery outcomes should use risk-adjusted results based on clinical data (728–735). *(Level of Evidence: B)*

See Online Data Supplement 31 for additional data on public reporting of cardiac surgery outcomes.

To address the need for valid and reliable risk-adjusted outcomes data, cardiac surgery registries were developed by the STS (306,725,727), Veterans Administration (306,736–738), Northern New England Cardiovascular Disease

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Study Group (739,740), and the state of New York (741,742). These have been the basis for several performance assessment and improvement strategies, including public report cards (742–744), confidential feedback to participants showing their performance relative to national benchmarks (306,737,745–748), and state or regional collaboratives that identify and disseminate best-practices information (749). Public report cards are the most controversial of these 3 approaches. Although they provide transparency and public accountability, it is unclear if they are the only or best way to improve quality. Reductions in the CABG mortality rate after the publication of such report cards in New York were encouraging (742,750–752), but subsequent studies revealed comparable reductions in other states, regions, and countries that used confidential feedback with or without performance improvement initiatives (752–754). These findings suggest that the common denominator among successful performance improvement strategies is the implementation of a formal quality assessment and feedback program benchmarked against regional or national results (755). The incremental value of public (as opposed to confidential) reporting is controversial.

Although providers fear the potential negative impact of public reporting on referrals and market share, this concern seems to be unfounded (756–765). Even when such impact has been observed, it has generally been modest, transient, and limited to areas populated by more affluent and educated subjects (760–762,766). With implementation of healthcare reform legislation that increases access of consumers and payers to objective data and more easily understood data presentations, the influence of public report cards is likely to increase in the future (762,767–771). As this occurs, it will be important to monitor unintended negative consequences, such as "gaming" of the reporting system (772) and avoidance of high-risk patients (risk aversion), the precise group of patients who are most likely to benefit from aggressive intervention (773–776).

Methodological considerations are important for provider profiling and public reporting. Numerous studies have shown the superiority of clinical over administrative data for these purposes (728–731,733,734). The latter data lack critical clinical variables that are necessary for adequate risk adjustment (732,735), they may confuse comorbidities and complications, and they may contain inaccurate case numbers and mortality rates. Outcomes measures, such as mortality, should always be adjusted for patient severity on admission (i.e., "risk-adjusted" or "risk-standardized") (777–780); otherwise, providers will be hesitant to care for severely ill patients, who are more likely to die from their disease. In addition, if a hospital or surgeon is found to be a low-performing outlier on the basis of unadjusted results, the hospital or surgeon may claim that their patients were sicker. Statistical methodologies should account for small sample sizes and clustered patient observations within institutions, and hierarchical or random-effects models have been advocated by some investigators (743,781–787). Point estimates of outcomes should always be accompanied by measures of statistical uncertainty, such as CIs. The units of analysis and reporting for provider profiling also have implications. Surgeon-level reports are published together with hospital reports in several states, but their smaller sample sizes typically require data aggregation over several years. Surgeon-level reporting may also increase the potential for risk aversion, as the anticipated worse results of the highest-risk patients are not diluted by the larger volume of a hospital or group. Finally, because the distribution of patient severity may vary substantially among providers, direct comparison of the results of one surgeon or hospital with those of another, even by using indirectly risk-standardized results, is often inappropriate (788). Rather, these results should be interpreted as comparisons of a provider's outcomes for his or her specific patient cohort versus what would have been expected had those patients been cared for by an "average" provider in the benchmark population.

Although risk-adjusted mortality rate has been the dominant performance metric in cardiac surgery for 2 decades, other more comprehensive approaches have been advocated (789). The STS CABG composite illustrates one such multidimensional approach, consisting of 11 National Quality Forum–endorsed measures of cardiothoracic surgery performance grouped within 4 domains of care (619,790).

5.1.1. Use of Outcomes or Volume as CABG Quality Measures: Recommendations

CLASS I

1. All cardiac surgery programs should participate in a state, regional, or national clinical data registry and should receive periodic reports of their risk-adjusted outcomes. *(Level of Evidence: C)*

CLASS IIa

1. When credible risk-adjusted outcomes data are not available, volume can be useful as a structural metric of CABG quality (309,751,791–798,800–804,807,818). *(Level of Evidence: B)*

CLASS IIb

1. Affiliation with a high-volume tertiary center might be considered by cardiac surgery programs that perform fewer than 125 CABG procedures annually. *(Level of Evidence: C)*

See Online Data Supplement 32 for additional data on outcomes or volume as CABG quality measures.

Numerous studies have demonstrated an association between hospital or individual practitioner volume and outcome for a variety of surgical procedures and some medical conditions (805–831). CABG was one of the original procedures for which this volume–outcome association was investigated (309,751,791–798,800–804,807,818). The CABG volume–outcome association is generally weaker than that of other procedures, such as esophagectomy or pancreatectomy, which are performed less often. In addition, the results of volume–outcome studies vary substantially according to methodology. The apparent strength of

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

the volume–outcome association often diminishes with proper risk adjustment based on clinical (as opposed to administrative) data (802,808). It is also weaker in more contemporary studies, presumably because of improved techniques and increasing experience (795,802). Finally, volume–outcome associations appear weaker when hierarchical models are used that properly account for small sample sizes and clustering of observations (832). The impact of CABG volume was studied in an observational cohort of 144,526 patients from 733 hospitals that participated in the STS Adult Cardiac Surgery Database in 2007 (309). In this analysis, a weak association between volume and unadjusted mortality rate was noted (2.6% unadjusted mortality rate for hospitals performing <100 procedures versus 1.7% for hospitals performing ≥450 procedures) (309). Using multivariate hierarchical regression, the largest OR (1.49) was found for the lowest-volume (<100 cases) group versus the highest-volume group. Desirable processes of care (except for use of the IMA) and morbidity rates were not associated with volume. The average STS-CABG composite score for the lowest-volume group (<100 cases per year) was significantly lower than that of the 2 highest-volume groups, but volume explained only 1% of variation in the composite score (619,790).

In general, the best results are achieved most consistently by high-volume surgeons in high-volume hospitals and the worst results by low-volume surgeons in low-volume hospitals (793,794). However, many low-volume programs achieve excellent results, perhaps related to appropriate case selection; effective teamwork among surgeons, nurses, anesthesiologists, perfusionists, and physician assistants; and adoption of best practices derived from larger programs (833,834).

As a quality assessment strategy, participation in a state, regional, or national clinical data registry that provides regular performance feedback reports is highly recommended for all cardiac programs. Random sampling variation is greater at low volumes (309,797,798,803,827,834,835), which complicates performance assessment of smaller programs. Several strategies may be considered to mitigate this measurement issue, including analysis over longer periods of time; appropriate statistical methodologies, such as hierarchical (random-effects) models; composite measures, which effectively increase the number of endpoints; and statistical quality control approaches, such as funnel plots (835) and cumulative sum plots (836–838). Small programs may benefit from direct supervision by a large tertiary center (834). Ultimately, state or national regulatory authorities must decide whether the lower average performance of very small programs and the added difficulty in accurately measuring their performance are outweighed by other considerations, such as the need to maintain cardiac surgery capabilities in rural areas with limited access to referral centers (834).

Volume, a structural quality metric, is an imperfect proxy for direct measurement of outcomes (822,839). Risk-adjusted outcomes based on clinical data are the preferred method of assessing CABG quality except in very low-volume programs, in which performance is generally weakest and small sample size makes accurate assessment of performance difficult.

5.2. Adverse Events

5.2.1. Adverse Cerebral Outcomes

5.2.1.1. STROKE

The incidence of stroke after CABG ranges from 1.4% to 3.8% (840), depending on the patient population and the criteria for diagnosis of stroke. Risk factors for stroke include advanced age, history of stroke, diabetes mellitus, hypertension (841), and female sex (842), with newer research emphasizing the importance of preoperative atherosclerotic disease (including radiographic evidence of previous stroke or aortic atheromatous disease) (843). Although macroembolization and microembolization are major sources of stroke, hypoperfusion (844), perhaps in conjunction with embolization (845), is a risk factor for postoperative stroke. The mortality rate is 10-fold higher among post-CABG patients with stroke than among those without it, and lengths of stay are longer in stroke patients (846).

Although off-pump CABG was introduced in large part to reduce stroke and other adverse neurological outcomes associated with CPB, several RCTs comparing on-pump and off-pump CABG have shown no difference in stroke rates (61,68,78,846a,846b,1069,1259).

See Online Data Supplement 33 for additional data on stroke rates.

5.2.1.1.1. USE OF EPIAORTIC ULTRASOUND IMAGING TO REDUCE STROKE RATES: RECOMMENDATION

CLASS IIa

1. **Routine epiaortic ultrasound scanning is reasonable to evaluate the presence, location, and severity of plaque in the ascending aorta to reduce the incidence of atheroembolic complications (847–849). (*Level of Evidence: B*)**

Identification of an atherosclerotic aorta is believed to be an important step in reducing the risk of stroke after CABG (850). Intraoperative assessment of the ascending aorta for detection of plaque by epiaortic ultrasound imaging is superior to direct palpation and TEE (851,852). Predictors of ascending aortic atherosclerosis include increasing age, hypertension, extracardiac atherosclerosis (peripheral artery and cerebrovascular disease), and elevated serum creatinine concentrations (853–855). Prospective RCTs to evaluate the role of epiaortic scanning in assessing stroke risk have not been reported, but several observational studies reported stroke rates of 0 to 1.4% (847–849,853,856,857) when surgical decision making was guided by the results of epiaortic scanning. Separate guidelines for the use of intraoperative epiaortic ultrasound imaging in cardiac surgery

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

were endorsed and published in 2008 by the American Society for Echocardiography, Society of Cardiovascular Anesthesiologists, and STS (147).

5.2.1.1.2. THE ROLE OF PREOPERATIVE CAROTID ARTERY NONINVASIVE SCREENING IN CABG PATIENTS: RECOMMENDATIONS

CLASS I

1. A multidisciplinary team approach (consisting of a cardiologist, cardiac surgeon, vascular surgeon, and neurologist) is recommended for patients with clinically significant carotid artery disease for whom CABG is planned. *(Level of Evidence: C)*

CLASS IIa

1. Carotid artery duplex scanning is reasonable in selected patients who are considered to have high-risk features (i.e., age >65 years, left main coronary stenosis, PAD, history of cerebrovascular disease [transient ischemic attack [TIA], stroke, etc.], hypertension, smoking, and diabetes mellitus) (858,859). *(Level of Evidence: C)*
2. In the CABG patient with a previous TIA or stroke and a significant (50% to 99%) carotid artery stenosis, it is reasonable to consider carotid revascularization in conjunction with CABG. In such an individual, the sequence and timing (simultaneous or staged) of carotid intervention and CABG should be determined by the patient's relative magnitudes of cerebral and myocardial dysfunction. *(Level of Evidence: C)*

CLASS IIb

1. In the patient scheduled to undergo CABG who has no history of TIA or stroke, carotid revascularization may be considered in the presence of bilateral severe (70% to 99%) carotid stenoses or a unilateral severe carotid stenosis with a contralateral occlusion. *(Level of Evidence: C)*

Because the presence of extracranial disease of the internal carotid artery is a risk factor for adverse neurological events after CABG (860), one might argue for use of carotid noninvasive scanning (duplex ultrasonography or noninvasive carotid screening) in all patients scheduled for CABG. At issue is the effectiveness of noninvasive carotid screening in identifying carotid artery stenoses of hemodynamic significance. Alternatively, the identification of preoperative risk factors known to be associated with the presence of carotid artery disease could be used to stratify patients into high- and low-risk categories, thereby allowing for a more selective use of noninvasive carotid screening. A retrospective analysis of 1,421 consecutive CABG patients identified the following as risk factors for significant carotid artery disease: age >65 years, presence of a carotid bruit, and a history of cerebrovascular disease (858). In so doing, they reduced preoperative testing by 40%, with only a "negligible" impact on surgical management or neurological outcomes. Similarly, the following risk factors have been identified as predicting the presence of >50% reduction in internal diameter of the internal carotid artery: smoking, diabetes mellitus, hypertension, a previous cerebrovascular event, PAD, left main CAD, and a history of cervical carotid disease (859). All subjects found to have significant carotid disease were noted to have ≥1 of these criteria. In addition, the probability of detecting significant carotid disease increased almost 3 times for each additional criterion that was present. The authors noted that the presence of a single preoperative risk factor increased the sensitivity of the screening test to 100% and increased the specificity to 30%. As a result, they strongly recommend a selective approach to the use of preoperative noninvasive carotid screening, allowing for a decrease in the number of unnecessary tests but exerting little effect on the detection of significant carotid disease.

In patients undergoing carotid endarterectomy, the rates of periprocedural stroke have been reported to be as high as 2.5% in those with asymptomatic carotid stenoses (861) and 5% in those with previous cerebrovascular symptoms (862). In CABG patients with >50% unilateral carotid stenoses in whom carotid endarterectomy is not performed concomitantly with CABG, the peri-CABG stroke rate is reportedly 3%, rising to 5% in those with bilateral carotid artery stenoses and 11% in those with an occluded carotid artery (860). In light of these data, the issue of combined carotid and coronary revascularization (performed simultaneously or in a staged, sequential fashion) as a strategy to reduce the postoperative stroke risk in CABG patients with known carotid artery disease has received substantial attention. The lack of clarity about the optimal approach to the management of such patients is the result of several factors:

- To date, no published randomized, prospective study has addressed this important clinical scenario (863).
- The etiology of postoperative stroke often is multifactorial (e.g., ascending aortic calcifications with resultant atherothrombotic embolization, preexisting carotid artery disease, air or debris cerebral embolization associated with CPB, episodes of transient intraoperative hypotension).
- Many risk factors for stroke coexist in CABG patients.
- The rates for postoperative stroke and death for carotid endarterectomy and for CABG, independent of or in conjunction with one another, vary considerably in different patient populations (e.g., young versus old, male versus female, etc.).
- More than half of all post-CABG strokes occur after uneventful recovery from CABG and are believed to be caused by supraventricular arrhythmias, low cardiac output, or postoperative hypercoagulability (863).
- A substantial proportion of post-CABG strokes occur in patients without significant carotid artery disease or in an anatomic distribution not consistent with a known significant carotid arterial stenosis.

Advances in technologies for carotid and coronary revascularization make the decision-making process for the procedures even more complex. In addition to conventional CABG with CPB, the surgeon may choose an off-pump technique in certain patients (e.g., those with a heavily calcified ascending aorta). Likewise, carotid artery stenting provides an alternative to endarterectomy, which may re-

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

duce the risk of postoperative stroke. Still, the ultimate impact of such stenting on postoperative stroke rates in CABG patients awaits the results of properly designed trials. At present, carotid artery stenting is reserved for CABG patients in whom a contraindication to open endarterectomy exists.

When combined carotid and coronary revascularization is indicated, an awareness of the stroke and mortality rates for different patient subgroups will help to guide decision making. Several factors favor combined revascularization, including (but not limited to) 1) severe carotid artery disease, 2) unfavorable morphological characteristics of the carotid lesion(s) (e.g., ulcerated lesions), 3) the presence of related symptoms, and 4) a history of TIA or stroke. In those with a history of TIA or stroke who have a significant carotid artery stenosis (50% to 99% in men or 70% to 99% in women), the likelihood of a post-CABG stroke is high; as a result, they are likely to benefit from carotid revascularization (863). Conversely, CABG alone can be performed safely in patients with asymptomatic unilateral carotid stenoses, because a carotid revascularization procedure offers no discernible reduction in the incidence of stroke or death in these individuals. Men with asymptomatic bilateral severe carotid stenoses (50% to 99%) or a unilateral severe stenosis in conjunction with a contralateral carotid artery occlusion may be considered for carotid revascularization in conjunction with CABG. Little evidence exists to suggest that women with asymptomatic carotid artery disease benefit from carotid revascularization in conjunction with CABG (864). Whether the carotid and coronary revascularization procedures are performed simultaneously or in a staged, sequential fashion is usually dictated by the presence or absence of certain clinical variables. In general, synchronous combined procedures are performed only in those with both cerebrovascular symptoms and ACS.

The optimal management of patients with coexisting carotid artery disease and CAD is poorly defined. Several therapeutic approaches can be used, including staged carotid endarterectomy and CABG, simultaneous carotid endarterectomy and CABG, or similar variations that use endovascular stenting as the primary carotid intervention. At present, no prospective RCTs comparing neurological outcomes after these different treatment strategies in patients with coexisting carotid artery disease and CAD have been reported (865).

5.2.1.2. DELIRIUM

The incidence of postoperative delirium after CABG is <10%, similar to that reported after noncardiac surgery (866–868). The risk factors for postoperative delirium are similar for cardiac and noncardiac surgery and include advanced age, preexisting cognitive impairment, and vascular disease (866,868,869). The burden of intraoperative cerebral microemboli does not predict the presence or severity of postoperative delirium (870). The development of postoperative delirium has been linked to functional decline at 1 month, short-term cognitive decline (871), and risk of late mortality (867,872).

5.2.1.3. POSTOPERATIVE COGNITIVE IMPAIRMENT

Short-term cognitive changes occur in some patients after on-pump CABG (873–875). The precise incidence depends on the timing of the postoperative assessment and the choice of criteria for cognitive decline (876,877). Similar short-term cognitive changes also are noted in elderly patients receiving general anesthesia for noncardiac surgery (878–880). Risk factors for short-term postoperative cognitive decline include preexisting risk factors for cerebrovascular disease (881), preexisting central nervous system disease (882), and preexisting cognitive impairment (75). Up to 30% of candidates for CABG have been shown to have cognitive impairment before surgery (75). A few studies have reported a lower incidence of short-term cognitive decline after off-pump CABG than on-pump CABG (883), but most studies have shown no difference in cognitive outcomes between them (884). Studies with appropriate comparison groups have demonstrated that most patients do not suffer cognitive decline after CABG (885,886). For those who do, the postoperative cognitive changes are generally mild, and for most patients, they resolve within 3 months of surgery (887).

Long-term cognitive decline after CABG has been reported (888,889), but other studies have shown that a similar degree of late cognitive decline occurs in comparison groups of demographically similar patients with CAD but without surgery, suggesting that the late decline is not related to the use of CPB (890). An RCT comparing late cognitive outcomes after on-pump and off-pump CABG has reported no difference between them (891).

See Online Data Supplement 34 for additional data on the role of perioperative cognitive impairment.

5.2.2. Mediastinitis/Perioperative Infection: Recommendations

CLASS I

1. Preoperative antibiotics should be administered to all patients to reduce the risk of postoperative infection (892–897). *(Level of Evidence: A)*
2. A second-generation cephalosporin is recommended for prophylaxis in patients without methicillin-resistant *Staphylococcus aureus* colonization (897–905). *(Level of Evidence: A)*
3. Vancomycin alone or in combination with other antibiotics to achieve broader coverage is recommended for prophylaxis in patients with proven or suspected methicillin-resistant *S. aureus* colonization (900,906–908). *(Level of Evidence: B)*
4. A deep sternal wound infection should be treated with aggressive surgical debridement in the absence of complicating circumstances. Primary or secondary closure with muscle or omental flap is recommended (909–911). Vacuum therapy in conjunction with early and aggressive debridement is an effective adjunctive therapy (912–921). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

5. Use of a continuous intravenous insulin protocol to achieve and maintain an early postoperative blood glucose concentration less than or equal to 180 mg/dL while avoiding hypoglycemia is indicated to reduce the risk of deep sternal wound infection (583,586,590,591,922,923). *(Level of Evidence: B)*

CLASS IIa

1. When blood transfusions are needed, leukocyte-filtered blood can be useful to reduce the rate of overall perioperative infection and in-hospital death (924–927). *(Level of Evidence: B)*
2. The use of intranasal mupirocin is reasonable in nasal carriers of *S. aureus* (928,929). *(Level of Evidence: A)*
3. The routine use of intranasal mupirocin is reasonable in patients who are not carriers of *S. aureus,* unless an allergy exists. *(Level of Evidence: C)*

CLASS IIb

1. The use of bilateral IMAs in patients with diabetes mellitus is associated with an increased risk of deep sternal wound infection, but it may be reasonable when the overall benefit to the patient outweighs this increased risk. *(Level of Evidence: C)*

See Online Data Supplements 35 and 36 for additional data on mediastinitis and perioperative infection.

Nosocomial infections occur in 10% to 20% of cardiac surgery patients. To prevent surgical site infections in CABG patients, a multimodality approach involving several perioperative interventions must be considered. Preoperative interventions include screening and decolonization of patients with methicillin-resistant and methicillin-sensitive *S. aureus* colonization and adequate preoperative preparation of the patient. Nasal carriage of *S. aureus* is a well-defined risk factor for subsequent infection. In proven nasal carriers of *S. aureus,* intranasal mupirocin reduces the rate of nosocomial *S. aureus* infection, but it does not reduce the rate of surgical site infection with *S. aureus* (928,929). Preoperative patient bathing, the use of topical antiseptic skin cleansers (chlorhexidine gluconate) (930–932), and proper hair removal techniques (using electric clippers or depilatories rather than razors) (933–937) are important measures with which to prepare the patient for surgery.

Intraoperative techniques to decrease infection include strict adherence to sterile technique, minimization of operating room traffic, less use of flash sterilization of surgical instruments, minimization of electrocautery (933,936) and bone wax (938), use of double-gloving (938–943), and shorter operative times. Identification of patients at high risk for preoperative infection allows the clinician to maximize prevention strategies. Superficial wound infection occurs in 2% to 6% of patients after cardiac surgery (656,944–946), and deep sternal wound infection occurs in 0.45% to 5%, with a mortality rate of 10% and 47% (947–953).

The etiology of deep sternal wound infection is multifactorial. Risk factors for deep sternal wound infection are diabetes mellitus (25,27,28), obesity (body mass index >30 kg/m^2) (947,949,950,953,954), chronic obstructive pulmonary disease (950), prolonged CPB time, reoperation, prolonged intubation time, and surgical reexploration (945,947,955). Potentially modifiable risk factors are smoking cessation, optimized nutritional status, adequate preoperative glycemic status (with hemoglobin A1c <6.9%), and weight loss. The use of bilateral IMAs has been a subject of investigation as a risk factor for deep sternal wound infection. Each IMA provides sternal branches, which provide 90% of the blood supply to each hemi-sternum. As a result, IMA harvesting can compromise sternal wound healing. Although no RCTs assessing the risk of deep sternal wound infection after bilateral IMA grafting have been reported, the use of bilateral IMAs in patients with diabetes and those with other risk factors for surgical site infection increases the incidence of deep sternal wound infection (956,957). Skeletonization of the IMA may be associated with a beneficial reduction in the incidence of sternal wound complications, more evident in patients with diabetes mellitus (958).

Transfusion of homologous blood is a risk factor for adverse outcomes after cardiac surgery. Blood transfusions after CABG are correlated in a dose-related fashion to an increased risk of transfusion-related infection, postoperative infection, postoperative morbidity, and early and late death (959–962). In addition, they have been associated with a higher incidence of sternal wound infections (949,963,964). In a retrospective analysis of 15,592 cardiovascular patients, the risk of septicemia/bacteremia and superficial and deep sternal wound infections increased incrementally with each unit of blood transfused (961). The leukocytes that are present in packed red blood cells induce the immunomodulatory effects associated with blood transfusions. Allogenic transfusions of blood containing leukocytes induce higher concentrations of proinflammatory mediators (such as interleukins 6 and 10) than does the transfusion of leukocyte-depleted blood (924–927,965). In patients undergoing cardiac surgery, RCTs have shown that those receiving leukocyte-filtered blood have lower rates of perioperative infection and in-hospital death than those receiving non–leukocyte-filtered blood (924–927). An RCT showed that those receiving leukocyte-depleted blood had a reduced rate of infection (17.9% versus 23.5%; p=0.04) and 60-day mortality (transfused/nonfiltered patient mortality rate, 7.8%; transfused/filtered at the time of donation, 3.6%; and transfused/filtered at the time of transfusion, 3.3% [p=0.019]) (927). Leukodepletion can be accomplished by the blood bank at the time of donation or at the bedside at the time of transfusion (with the use of an inexpensive in-line transfusion filter). Preoperative antibiotics reduce the risk of postoperative infection 5-fold (892). Interest has grown in administering antibiotic prophylaxis as a single dose rather than as a multiple-dosing regimen for 24 to 48 hours, because single-dose antibiotic prophylaxis reduces the duration of prophylaxis, its cost, and the likelihood of antimicrobial resistance.

Staphylococcus coagulase–negative epidermidis or *S. aureus* (including methicillin-resistant *S. aureus*) account for 50% of surgical site infections. Other organisms that are often

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

involved are *Corynebacterium* and enteric gram-negative bacilli (966–968). Antibiotic prophylaxis against these organisms should be initiated 30 to 60 minutes before surgery, usually at the time of anesthetic induction, except for vancomycin, which should be started 2 hours before surgery and infused slowly to avoid the release of histamine (903,969,970). In patients without methicillin-resistant *S. aureus* colonization, a cephalosporin (cefazolin, 1 g given intravenously every 6 hours, or cefuroxime, 1.5 g given intravenously every 12 hours) is the agent of choice for standard CABG (897–905). Antibiotic redosing is performed if the operation lasts >3 hours (970). Vancomycin is reserved for the patient who is allergic to cephalosporins or has known or presumed methicillin-resistant *S. aureus* colonization (900,906–908).

The incidence of deep sternal wound infection has decreased over the past 15 years despite an increased risk profile of patients undergoing cardiac surgery (i.e., increased comorbidities, obesity, diabetes mellitus, and advanced age) (971). Several options are available for the treatment of deep sternal wound infection. The main treatment is surgical debridement with primary or delayed reconstruction with vascularized soft tissue (pectoral muscle or omentum) (909–912,972). Conventional treatment with pectoralis flap muscle or omentum is associated with procedure-related morbidities, such as destabilization of the thoracic cage, surgical trauma, and potential failure of the flap. In current practice, the vacuum-assisted closure system is often used in the treatment of mediastinitis (913). With it, local negative pressure is applied to the open wound, accelerating granulation tissue formation and increasing blood supply. Such vacuum-assisted closure therapy, which is less invasive than conventional surgical treatment, has been used as standalone therapy, as a bridge to flap advancement, or as sternal preconditioning and preservation followed by titanium plate sternal osteosynthesis (913,914,973). Although several studies have suggested that vacuum-assisted closure therapy can be a successful alternative to conventional standard therapy (913–921,973), the data are from single-center retrospective studies of patients with heterogeneous disease processes. As a result, it seems reasonable to suggest that both conventional and vacuum-assisted closure therapy can be used in the treatment of mediastinitis.

5.2.3. Renal Dysfunction: Recommendations

CLASS IIb

1. In patients with preoperative renal dysfunction (creatinine clearance <60 mL/min), off-pump CABG may be reasonable to reduce the risk of acute kidney injury (AKI) (974–978). *(Level of Evidence: B)*
2. In patients with preexisting renal dysfunction undergoing on-pump CABG, maintenance of a perioperative hematocrit greater than 19% and mean arterial pressure greater than 60 mm Hg may be reasonable. *(Level of Evidence: C)*
3. In patients with preexisting renal dysfunction, a delay of surgery after coronary angiography may be reasonable until the effect of radiographic contrast material on renal function is assessed (979–981). *(Level of Evidence: B)*
4. The effectiveness of pharmacological agents to provide renal protection during cardiac surgery is uncertain (982–1004). *(Level of Evidence: B)*

See Online Data Supplements 37 to 39 for additional data on CABG and renal dysfunction.

Depending on the definition used, the incidence of AKI (defined in various studies as an increase in serum creatinine concentration and/or decrease in calculated glomerular filtration rate of a certain magnitude) after isolated CABG is 2% to 3%, and the incidence of AKI requiring dialysis is 1% (1005). Risks factors for developing AKI after CABG are preoperative renal dysfunction, LV systolic dysfunction, PAD, advanced age, race, female sex, type of surgery, diabetes mellitus requiring insulin, emergency surgery, preoperative intraaortic balloon support, and congestive heart failure or shock (1005–1013).

The pathogenesis of postoperative AKI is usually multifactorial. The identification and effective management of modifiable variables can minimize its occurrence. CPB can lead to renal dysfunction if renal perfusion is not adequately maintained. In addition, CPB leads to a systemic inflammatory response, with the release of 1) inflammatory cytokines (e.g., kallikrein, bradykinin), 2) catecholamines, and 3) other hormones (e.g., renin, aldosterone, angiotensin II, vasopressin), all of which influence renal function. The effects of hypothermia during CPB on renal function are uncertain. Two RCTs (1014,1015) showed no effect of CPB temperature on renal function in patients undergoing CABG, whereas a 2010 observational study (1016) of 1,072 subjects identified a relationship between a CPB temperature <27°C and the development of AKI (OR: 1.66; 95% CI: 1.16 to 2.39; p=0.005). Although off-pump CABG may theoretically avoid CPB-related renal injury, the cardiac manipulation that is often required to obtain adequate exposure may cause transient decreases in cardiac output, increased peripheral vasoconstriction, and decreased renal perfusion (1017). A meta-analysis of 6 RCTs and 16 observational studies (encompassing data from 27,806 patients) suggested a modest beneficial effect of off-pump CABG in reducing the incidence of AKI but no advantage in reducing the incidence of AKI–dialysis (977). These findings were confirmed by another published RCT of 2,203 patients, in which the incidence of AKI–dialysis was similar among those undergoing off-pump and on-pump CABG (0.8% for off pump; 0.9% for on pump; p=0.82) (61). Considering the low (approximately 1%) incidence of AKI–dialysis in subjects undergoing CABG, available RCTs are underpowered to detect a difference in outcome. In patients with renal dysfunction preoperatively, it might be reasonable to perform off-pump CABG to reduce the risk of AKI (974–976,978,996). During CPB, hemodilution is induced to reduce blood viscosity and plasma oncotic

ARTICLE IN PRESS

pressure to improve regional blood flow in the setting of hypothermia and hypoperfusion. However, an excessively low hematocrit on CPB is associated with increased adverse events and in-hospital deaths (1018). In patients undergoing isolated CABG, it has been reported that the mortality rate of patients with a single hematocrit value <19% was twice that of those with a hematocrit of 25% (1019). On the basis of these data, a hematocrit <19% on CPB should be avoided.

No drugs have been identified that prevent or alleviate CABG-associated AKI. N-acetylcysteine reduces proinflammatory cytokine release, oxygen free radical generation, and reperfusion injury, but a review of 10 RCTs containing data from 1,163 patients (982) showed that it did not reduce the incidence of AKI and AKI–dialysis (987). In several RCTs, atrial natriuretic peptide was shown to reduce peak postoperative serum creatinine concentrations, increase urine output, and reduce the need for dialysis in individuals with normal renal function preoperatively, but it did not prevent AKI–dialysis in patients with preexisting renal dysfunction (996).

Fenoldopam, a selective dopamine D_1 receptor agonist that causes vasodilatation and increases renal cortical and outer medullary blood flow, seems to exert protective renal effects in critically ill patients (994,995). A meta-analysis of the data from 1,059 patients reported in 13 randomized and case-matched studies showed that fenoldopam exerts a beneficial effect on renal function. Compared with standard therapy, fenoldopam reduced the need for renal replacement therapy (5.7% versus 13.4%; OR: 0.37; 95% CI: 0.23 to 0.59; $p<0.001$) and lowered the peak value for serum creatinine concentration. Nevertheless, this beneficial effect was counterbalanced by an increased rate of hypotension and vasopressor requirements (15% versus 10.2%; OR: 1.94; 95% CI: 1.1.9 to 3.16; $p=0.008$). Dopamine at low doses increases renal blood flow and blocks the tubular reabsorption of sodium. A meta-analysis on the use of low-dose dopamine reported that it increased urine output and improved serum creatinine concentrations without influencing the need for renal replacement therapy or the rates of adverse events or death (990).

Diltiazem and mannitol have been used to prevent AKI after cardiac surgery (988). Diltiazem may inhibit the inflammatory response that occurs with CPB (992), whereas mannitol produces an osmotic diuresis (1000). The role of mannitol in preventing AKI is unclear (983,1004). Diltiazem does not prevent renal dysfunction (983). Contrast-induced nephropathy is a common cause of AKI. It is usually self-limited and manifests its peak effect 3 to 5 days after the administration of contrast material. In patients with preoperative renal dysfunction, it is reasonable to delay surgery for several days after coronary angiography to reduce the incidence of AKI (979–981).

5.2.4. Perioperative Myocardial Dysfunction: Recommendations

CLASS IIa

1. **In the absence of severe, symptomatic aorto-iliac occlusive disease or PAD, the insertion of an intraaortic balloon is reasonable to reduce mortality rate in CABG patients who are considered to be at high risk (e.g., those who are undergoing reoperation or have LVEF <30% or left main CAD) (1021–1026). *(Level of Evidence: B)***
2. **Measurement of biomarkers of myonecrosis (e.g., creatine kinase-MB, troponin) is reasonable in the first 24 hours after CABG (200). *(Level of Evidence: B)***

Intraaortic balloon counterpulsation is an established mechanical cardiac support procedure that has been demonstrated to increase cardiac output and to improve coronary blood flow (1025,1026). In several RCTs, its preoperative initiation and perioperative use have been shown to reduce the mortality rate in CABG patients who are considered to be at high risk (i.e., those undergoing repeat CABG, those with an LVEF <30%, or those with left main CAD) (1022–1024) despite its known associated vascular complications (1021). In contrast, its routine use in subjects who are not thought to be high risk has not been demonstrated (1027).

Some myocyte necrosis often occurs during and immediately after CABG, caused by cardiac manipulation, inadequate myocardial protection, intraoperative defibrillation, or acute graft failure. A determination of the frequency and magnitude with which postoperative myonecrosis occurs has been difficult. In 2007, the European Society of Cardiology/ACCF/AHA/World Heart Federation Task Force for the Redefinition of Myocardial Infarction stated, "[B]iomarker values more than 5 times the 99th percentile of the normal reference range during the first 72 h following CABG, when associated with the appearance of new pathological Q-waves or new [left bundle branch block], or angiographically documented new graft or native coronary artery occlusion, or imaging evidence of new loss of viable myocardium should be considered as diagnostic of a CABG-related myocardial infarction (type 5 myocardial infarction)" (203, p. 2183). Until 2000, the conventional biomarker for myonecrosis was creatine kinase-MB, but at present cardiac-specific troponin is the preferred indicator of myonecrosis (198,200). The higher the serum concentrations of biomarkers after CABG, the greater the amount of myonecrosis and, therefore, the greater the likelihood of an adverse outcome.

Published data from the PREVENT IV trial suggest, first, that serum biomarkers for myonecrosis are elevated postoperatively even in roughly 10% of CABG subjects who are considered to be low risk for the procedure and, second, that short-term (30-day) and long-term (2-year) outcomes were worse in these patients than in those without a postoperative biomarker elevation. Similarly, a direct correlation has been noted between the presence and magnitude

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

of biomarker elevations postoperatively and both intermediate- and long-term risk of death (1028).

5.2.4.1. TRANSFUSION: RECOMMENDATION

CLASS I

1. **Aggressive attempts at blood conservation are indicated to limit hemodilutional anemia and the need for intraoperative and perioperative allogeneic red blood cell transfusion in CABG patients (1029–1032). *(Level of Evidence: B)***

Numerous large observational studies have identified perioperative allogeneic red blood cell transfusion(s) as an independent risk factor for adverse outcomes, including death (1029–1032). A prospective observational study of 8,004 patients demonstrated that the transfusion of allogeneic red blood cells in CABG patients was associated with an increased risk of low-output heart failure irrespective of the extent of hemodilutional anemia (1030). An adverse outcome may be caused by immunomodulation (known to occur with red blood cell transfusion), initiation of a systemic inflammatory response and its associated direct negative myocardial effects, reduced red blood cell capacity for adequate oxygen delivery (1031,1032) (diphosphoglycerate function in "banked" blood may cause tissue hypoxia), and changes in red blood cell morphology of transfused blood. Regardless of etiology, myocardial depression is observed consistently after allogeneic red blood cell transfusion, and this effect appears to be dose dependent. Even risk-adjusted survival rates after CABG in patients transfused with allogeneic red blood cells are reduced (1029–1032).

5.2.5. Perioperative Dysrhythmias: Recommendations

CLASS I

1. **Beta blockers should be administered for at least 24 hours before CABG to all patients without contraindications to reduce the incidence or clinical sequelae of postoperative AF (604–608,608a–608c). *(Level of Evidence: B)***
2. **Beta blockers should be reinstituted as soon as possible after CABG in all patients without contraindications to reduce the incidence or clinical sequelae of AF (604–608,608a–608c). *(Level of Evidence: B)***

CLASS IIa

1. **Preoperative administration of amiodarone to reduce the incidence of postoperative AF is reasonable for patients at high risk for postoperative AF who have contraindications to beta blockers (1036). *(Level of Evidence: B)***
2. **Digoxin and nondihydropyridine calcium channel blockers can be useful to control the ventricular rate in the setting of AF but are not indicated for prophylaxis (606,1037–1041). *(Level of Evidence: B)***

AF immediately after CABG, occurring in 20% to 50% of patients, is often difficult to manage and is associated with a substantially increased risk of morbidity (particularly disabling embolic events) and mortality. A prospective observational study of 1,878 consecutive subjects undergoing CABG noted that post-CABG AF was associated with a 4-fold increased risk of disabling embolic stroke and a 3-fold increased risk of cardiac-related death (607).

The incidence of postoperative AF is increased in the presence of advanced patient age, male sex, PAD, chronic lung disease, concomitant valvular heart disease, left atrial enlargement, previous cardiac surgery, preoperative atrial tachyarrhythmias, pericarditis, and elevated postoperative adrenergic tone. However, many subjects have none of these factors, yet they develop AF in the immediate postoperative period. Postoperative AF almost always occurs within 5 days postoperatively, with a peak incidence on the second postoperative day (608). Numerous trials have assessed the efficacy of various pharmacologic agents in preventing post-CABG AF, including beta-adrenergic-blockers, various antiarrhythmic agents, glucocorticosteroids, hormonal agents (e.g., triiodothyronine), and even statins. Preoperative and postoperative beta blockers (or possibly amiodarone) are most effective at reducing its incidence, with several RCTs showing that they effectively accomplish this goal. In contrast, glucocorticosteroids, hormonal agents, and statins are not effective at decreasing its occurrence (604–606,608b,608c,1042). In subjects without pre-CABG AF, post-CABG AF usually resolves spontaneously within 6 weeks of surgery. As a result, the preferred management strategy of post-CABG AF in such patients often consists of control of the ventricular rate (with beta blockers) in anticipation of spontaneous reversion to sinus rhythm within a few weeks. In addition, if the patient is considered to be at risk for a thromboembolic event while in AF, anticoagulation (with heparin and then warfarin) is warranted. For a more detailed description of the management of subjects with postoperative AF, the reader is referred to the 2011 ACCF/AHA/HRS guidelines for the Management of Patients with Atrial Fibrillation (608).

5.2.6. Perioperative Bleeding/Transfusion: Recommendations

CLASS I

1. **Lysine analogues are useful intraoperatively and postoperatively in patients undergoing on-pump CABG to reduce perioperative blood loss and transfusion requirements (1044–1051). *(Level of Evidence: A)***
2. **A multimodal approach with transfusion algorithms, point-of-care testing, and a focused blood conservation strategy should be used to limit the number of transfusions (1052–1057). *(Level of Evidence: A)***
3. **In patients taking thienopyridines (clopidogrel or prasugrel) or ticagrelor in whom elective CABG is planned, clopidogrel and ticagrelor should be withheld for at least 5 days (520,521,523,524, 531,1058–1063) *(Level of Evidence: B)* and prasugrel for at least 7 days (533) *(Level of Evidence: C)* before surgery.**
4. **It is recommended that surgery be delayed after the administration of streptokinase, urokinase, and tissue-type plasminogen activators until hemostatic capacity is restored, if possible. The timing of recommended delay should be guided by the pharmacodynamic half-life of the involved agent. *(Level of Evidence: C)***
5. **Tirofiban or eptifibatide should be discontinued at least 2 to 4 hours before CABG and abciximab at least 12 hours before CABG (526–528,1049,1050,1064–1068). *(Level of Evidence: B)***

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

CLASS IIa

1. It is reasonable to consider off-pump CABG to reduce perioperative bleeding and allogeneic blood transfusion (67,1069–1074). *(Level of Evidence: A)*

See Online Data Supplements 40 to 42 for additional data on bleeding/transfusion.

Approximately 10% of allogeneic blood transfusions in the United States are given to subjects undergoing cardiac surgery (1075). Allogeneic transfusion carries the risks of transfusion reactions, air-borne infections, and increased hospital costs. In patients undergoing isolated CABG, transfusions are associated with reduced long-term survival and worse quality of life (1029,1076).

About 10% to 20% of the cardiac patients who are transfused receive roughly 80% of the transfusions that are administered (1075,1078). These high-risk patients often can be identified preoperatively to facilitate measures directed at blood conservation. Several reports have identified risk factors for blood transfusions (1079–1082), including advanced age, preoperative anemia, small body size, reoperative CABG, priority of operation, duration of CPB, presence of preoperative coagulopathy, and preoperative antithrombotic therapy (1080,1083–1088). A multimodal approach that includes transfusion algorithms, point-of-care testing, and a focused blood conservation strategy can limit the percentage of patients requiring transfusion and the amount of blood transfusions per patient (1052–1057).

About 60% to 70% of CABG patients are taking aspirin at the time of the procedure (536,1089,1090). Although aspirin increases perioperative blood loss and blood transfusion requirements (1091–1098), the amount of blood loss can be minimized by avoiding CPB (1099) and by using blood conservation techniques. In a meta-analysis of data from 805 patients (1100), doses of preoperative aspirin >325 mg were associated with increased bleeding (mean difference, 230 mL), whereas those who received <325 mg preoperatively did not have a significant increase in blood loss (mean difference: 65.3 mL; 95% CI: 20.2 to 150.8; p=0.134).

Some subjects undergoing CABG are receiving DAPT. Multiple studies have shown that the preoperative use of aspirin and clopidogrel is associated with increased perioperative bleeding, transfusions, and required reexploration for bleeding (522–524,531,1058–1062,1101–1107). In a study of 350 CABG patients at 14 centers, the risk of reexploration for bleeding was increased 3-fold in patients who were exposed to clopidogrel within 5 days of surgery; half of these patients required transfusions (520). In patients taking clopidogrel in whom elective CABG is planned, the drug should be withheld for 5 to 7 days before surgery. In subjects taking DAPT because of previous placement of a DES, clopidogrel can be stopped 1 year after the most recent DES placement. If CABG cannot be postponed, some operators have suggested that the patient be hospitalized for conversion of thienopyridine therapy to short-acting glycoprotein IIb/IIIa inhibitors for several days before surgery (497,1063,1108,1109); however, no data are available demonstrating the efficacy of such a management strategy. Streptokinase, urokinase, and tissue-type plasminogen activator should be stopped before CABG; in these individuals, the timing of CABG depends on the pharmacodynamic half-life of the agent involved (1110).

The use of unfractionated heparin has not been associated with increased perioperative blood loss; it can be continued until a few hours before CABG. Low-molecular-weight heparin can be administered safely ≤12 hours preoperatively and does not result in excessive perioperative blood loss (1064–1068). Lysine analogues, such as epsilon-aminocaproic acid and tranexamic acid, inhibit fibrinolysis by binding to the plasminogen molecule. Several trials have shown that both epsilon-aminocaproic acid and tranexamic acid reduce blood loss and blood transfusions during cardiac surgery, but they do not reduce the rate of reexploration for bleeding (1044–1051). Both drugs appear to be safe and do not increase the risk of death (1111).

Erythropoietin is a glycoprotein hormone that stimulates red blood cell production. Recombinant human erythropoietin is used in combination with iron supplementation to treat anemic patients (hemoglobin levels <13 g/dL) with renal failure and those undergoing chemotherapy. The use of erythropoietin in cardiac surgery has been studied in 12 RCTs and has been shown to be associated with significant risk reduction in allogeneic blood transfusion after cardiac surgery (1112–1122). However, the data from the RCTs are heterogeneous, with different doses of erythropoietin administered for 1 to 3 weeks preoperatively; as a result, further studies are needed to define more precisely the patient subgroups who may benefit from this therapy (1123). In patients who refuse blood transfusions during cardiac surgery, a short-term course of preoperative erythropoietin, to produce a high hematocrit preoperatively, may be administered (1124,1125). Alternatively, autologous blood donation may be used, which consists of extracting 1 to 3 units during the 30 days preoperatively and then reinfusing it during or postoperatively. However, such a practice is uncommon because of the increased risk of hemodynamic instability.

Off-pump CABG may avoid CPB-related coagulopathy caused by exposure of blood to artificial surfaces, mechanical trauma, alterations in temperature, and hemodilution. Some evidence suggests that off-pump CABG is associated with less bleeding and fewer blood transfusions (67,1069–1074).

6. Specific Patient Subsets

6.1. Elderly

The term "elderly" in CABG patients is usually defined as ≥80 years of age. Compared with younger subjects, the elderly are more likely to have severe (left main or multivessel) CAD, LV systolic dysfunction, concomitant valvular

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

disease, and previous sternotomy. In addition, they often have comorbid conditions, such as diabetes mellitus, hypertension, chronic obstructive pulmonary disease, PAD, and azotemia. As a result, the elderly have a higher perioperative risk of morbidity and mortality than do younger patients receiving CABG. The operative mortality rate among the elderly ranges from 2.6% (in a population >75 years of age) to 11% (in a population >80 years of age undergoing urgent or emergency surgery) (298,1126). Retrospective studies have observed a substantially higher in-hospital mortality rate among octogenarians than among younger patients (1127–1130). A report from the National Cardiovascular Network of outcomes in 67,764 patients undergoing cardiac surgery, of whom 4,743 were octogenarians, showed that the in-hospital mortality rate for the octogenarians was substantially higher (3.0% versus 8.1%; $p<0.001$) (1127).

Several retrospective studies of patients undergoing CABG have reported a higher incidence of neurological complications, renal failure, respiratory failure, and gastrointestinal complications among octogenarians than among younger subjects (298,1127,1128). In addition, the elderly have longer lengths of stay and are less likely to be discharged home. An analysis of the New York State Department of Health Cardiac Reporting System registry revealed that length of stay after CABG was 8.5 days in patients <50 years of age and 14.1 days in those >80 years of age, with discharge-to-home rates of 96% and 52%, respectively (1126).

Despite higher rates of in-hospital morbidity and mortality, the majority of octogenarians achieve functional improvement after CABG. Two studies of patients ≥80 years of age demonstrated improvements in quality of life, as assessed by the Seattle Angina Questionnaire (1131,1132). In 1 of these, angina relief and quality-of-life improvement scores after CABG did not differ between patients >75 and ≤75 years of age (1126). Of 136 octogenarians who underwent CABG, 81% felt that they were left with little or no disability in their daily activities, and 93% reported substantial symptomatic improvement an average of 2.1 years postoperatively (1131).

6.2. Women

Data on the influence of sex on CABG outcomes are limited. The BARI (Bypass Angioplasty Revascularization Investigation) study compared the outcomes of 1,829 patients with multivessel CAD randomly assigned to receive CABG or PCI; 27% were women (1133). Most information on the efficacy of CABG comes from studies done primarily in men, with extrapolation of the results to women. Although long-term outcomes with CABG in women are similar to or even better than those in men, women have higher rates of periprocedural morbidity and mortality (1133–1139). Several hypotheses have been suggested to explain this increased morbidity and mortality, including older age at presentation, more frequent need for urgent revascularization, more comorbid conditions, smaller body surface area and coronary arterial dimensions, and increased risk of bleeding. The fact that women on average are older than men at the time of CABG is thought, at least in part, to be due to the loss of the protective effects of estrogen with menopause (1134,1138,1140–1148). In studies of age-matched men and women undergoing CABG, in-hospital mortality rates were similar, even among the elderly (≥70 years of age) (1149,1150).

In addition to being older, women undergoing CABG are more likely than men to have ACS and cardiogenic shock (1140) and, therefore, to require urgent revascularization (1138,1141–1143,1146,1148). Sex disparity in the diagnosis and treatment of CAD may contribute to the more complex and delayed presentations in women compared with men (1151). In comparison to men, women are less likely to be referred for coronary angiography and revascularization and are more likely to have refractory ischemia and repeated hospitalizations (1152).

Compared with men undergoing CABG, women have more comorbid conditions, including diabetes mellitus, hypertension, hyperlipidemia, chronic renal insufficiency, chronic obstructive pulmonary disease, and concomitant valvular disease (1153). In some studies, no significant difference in outcomes between women and men undergoing CABG was noted when the data were adjusted for age and comorbidities (1136–1138,1154–1156), whereas in others, female sex remained an independent predictor of a worse outcome (1141,1157,1158). In a systematic review of sex differences and mortality after CABG, early mortality differences were reduced but not eliminated after adjustment for comorbidities, procedural characteristics, and body habitus (1139). Some investigators have shown that smaller body surface area, a surrogate for coronary arterial size, is associated with higher risk of perioperative mortality, whereas others have not (1140).

Women use more hospital resources in the perioperative period than do men, including intra-aortic balloon counterpulsation (1137), vasopressors, mechanical ventilation, dialysis, and blood products (1154,1159), all of which are associated with higher mortality rates (1146,1160,1161). Women are more likely to have wound complications and longer ICU and hospital stays (1162–1165). Lastly, the operative procedure itself appears to be different in women than in men, in that women are less likely to be completely revascularized (1166,1167) and less likely to have IMA grafting, especially bilateral (1168), even though bilateral IMA grafting in women is associated with low rates of in-hospital morbidity and mortality (1169).

6.3. Patients With Diabetes Mellitus

The prevalence of diabetes mellitus in CABG patients has increased markedly over the past 30 years. In the late 1970s, only 10% to 15% of CABG patients had diabetes (1170); by 2005, the incidence had risen to 35% (308). Patients with diabetes, especially those who are insulin dependent, have higher rates of perioperative morbidity and mortality and a

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

reduced long-term survival rate than those without diabetes (308,1171,1172). In the STS Registry, patients with diabetes on oral therapy had an adjusted OR of 1.15 for death within 30 days of CABG (95% CI: 1.09 to 1.21) as well as a greater likelihood of stroke, renal failure, and deep sternal wound infection than those without diabetes (308). For subjects receiving insulin, the adjusted OR for death within 30 days was 1.50 (95% CI: 1.42 to 1.58), and the risks for other complications were correspondingly higher. The poorer short-term outcome in patients with diabetes is only partly explained by a greater frequency of other comorbid conditions, such as obesity, hypertension, renal insufficiency, PAD, and cerebrovascular disease. The reduced long-term survival rate after CABG in patients with diabetes is likely due to a combination of more rapid progression of atherosclerosis, a lower long-term patency rate of SVGs (1173), and a greater burden of comorbid conditions. As in patients without diabetes, long-term outcome after CABG is better when an IMA is used as a conduit than when CABG is performed with only SVGs (362).

A subgroup analysis of data from the BARI trial suggested that patients with diabetes who underwent CABG with 1 arterial conduit had improved survival compared with those who underwent PCI (516). Several subsequent observational and cohort studies also showed that CABG results in better long-term outcome in patients with diabetes and multivessel CAD compared with balloon angioplasty or BMS implantation (361,451,1174). A meta-analysis of 10 RCTs comparing CABG with balloon angioplasty (n=6) or BMS implantation (n=4) concluded that the mortality rate was substantially lower in patients with diabetes undergoing CABG (451).

Little information is available about CABG versus PCI with DES in patients with diabetes mellitus. The results of CARDia (Coronary Artery Revascularisation in Diabetes), the first RCT comparing CABG and PCI in a population consisting entirely of subjects with diabetes, suggested that PCI with DES (used in 69% of the PCI patients) and CABG achieved similar outcomes (475). Of the 1,800 subjects enrolled in the SYNTAX trial, which compared CABG and PCI with paclitaxel-eluting stents, 452 had medically treated diabetes (364). At 1-year follow-up, the 2 treatments exerted a similar effect on survival, MI, and the composite endpoint of death, MI, or stroke. As in the entire SYNTAX cohort, patients with diabetes randomly assigned to receive PCI had a higher rate of repeat revascularization (20.3% after PCI versus 6.4% after CABG; $p<0.001$), and those with highly complex lesions (i.e., SYNTAX score $\geq$33) had a higher mortality rate with PCI (13.5% versus 4.1%; $p=0.04$). The FREEDOM (Future Revascularization Evaluation in patients with Diabetes mellitus: Optimal management of Multivessel disease) trial, an ongoing randomized comparison of CABG and PCI with DES in 1,900 patients with diabetes and multivessel CAD, should shed further light on the preferred therapy for these patients (1175).

Few comparisons of CABG and contemporary medical therapy in patients with diabetes mellitus are of sufficient size to allow meaningful conclusions. The largest such trial, BARI 2D, randomly assigned 2,368 patients with type 2 diabetes mellitus to revascularization plus intensive medical therapy or intensive medical therapy alone (404,1176), with patients in the medical therapy group to undergo revascularization during follow-up only if such therapy were clinically indicated by the progression of angina or the development of an ACS or severe ischemia. The planned method of revascularization, PCI or CABG, was determined before randomization by the treating physicians. No significant difference in primary endpoints was evident between the PCI group and the medical therapy group. No difference in survival rate between those undergoing CABG and those receiving only medical therapy was noted. Acute MI occurred less often in those assigned to CABG plus intensive medical therapy than in those given intensive medical therapy alone (10% versus 17.6%; $p=0.003$), and the composite endpoints of death or MI (21.1% versus 29.2%; $p=0.01$) and cardiac death or MI also occurred less often (1176). Compared to those selected for PCI, the CABG patients had more 3-vessel CAD (52% versus 20%), more totally occluded arteries (61% versus 32%), more proximal LAD artery stenoses >50% (19% versus 10%), and a higher myocardial jeopardy score.

Elevated fasting blood glucose concentrations before CABG and persistently elevated glucose concentrations afterward are associated with increased risk of morbidity and mortality (592,1177,1178). The complications most closely linked to postoperative hyperglycemia are infections, including deep sternal wound infection and mediastinitis. Achieving glycemic control perioperatively in patients with diabetes decreases this risk (581,593). Because the risk of deep sternal wound infection in patients with diabetes is increased when both IMAs are harvested and used, bilateral IMA grafting is not recommended in this patient cohort unless the overall benefit to the patient outweighs this increased risk (957).

6.4. Anomalous Coronary Arteries: Recommendations

CLASS I

1. Coronary revascularization should be performed in patients with:
   a. A left main coronary artery that arises anomalously and then courses between the aorta and pulmonary artery (1179–1181). *(Level of Evidence: B)*
   b. A right coronary artery that arises anomalously and then courses between the aorta and pulmonary artery with evidence of myocardial ischemia (1179–1182). *(Level of Evidence: B)*

CLASS IIb

1. Coronary revascularization may be reasonable in patients with a LAD coronary artery that arises anomalously and then courses between the aorta and pulmonary artery. *(Level of Evidence: C)*

Several variations and anatomic courses of anomalous coronary arteries have been described, some benign and others

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

associated with sudden cardiac death. The most life-threatening variants involve anomalous origin of the left main coronary artery from the right sinus of Valsalva or of the right coronary artery from the left sinus of Valsalva, after which the anomalous artery travels to its normal area of perfusion between the ascending aorta and the main pulmonary artery. In a review of consecutive echocardiograms in 2,388 asymptomatic children and young adolescents, the incidence of anomalous coronary arteries arising from the opposite sinus of Valsalva was 0.17% (1183). Anomalous coronary arteries (particularly those traversing between the aorta and the main pulmonary artery) are associated with exercise-related sudden death in young (≤35 years of age) athletes (1184–1190). A consecutive series of 27 young athletes with sudden death who were found to have such anomalous coronary arteries at autopsy had inducible myocardial ischemia and complained of cardiac symptoms before their demise (1179). Isolated case reports of other coronary arterial anomalies in subjects with syncope or sudden death emphasize the need for careful anatomic and functional evaluation of all individuals with anomalous coronary arteries (1191–1194). The method of revascularization employed in adults with anomalous coronary arteries has been 1) CABG or, more recently, 2) PCI with stenting (1195). When CABG is employed, consideration should be given to the presence of competitive flow in the native coronary circulation (1196). In children and some adults, an unroofing procedure or coronary arterial reimplantation may provide the best long term results (1197,1198). The risk associated with these coronary anomalies if they are left untreated and the existing operative experience make corrective surgery reasonable in these individuals (1180).

6.5. Patients With Chronic Obstructive Pulmonary Disease/Respiratory Insufficiency: Recommendations

CLASS IIa

1. Preoperative intensive inspiratory muscle training is reasonable to reduce the incidence of pulmonary complications in patients at high risk for respiratory complications after CABG (1199). *(Level of Evidence: B)*

CLASS IIb

1. After CABG, noninvasive positive pressure ventilation may be reasonable to improve pulmonary mechanics and to reduce the need for reintubation (1200,1201). *(Level of Evidence: B)*
2. High thoracic epidural analgesia may be considered to improve lung function after CABG (37,1202). *(Level of Evidence: B)*

See Online Data Supplement 43 for additional data on patients with chronic obstructive pulmonary disease/respiratory insufficiency.

In the STS Adult Cardiac Database predictive algorithms, the presence of chronic obstructive pulmonary disease preoperatively was an independent predictor of mortality, the need for prolonged postoperative ventilator support, and renal failure (1203). Furthermore, most rehospitalizations following CABG are related to pulmonary dysfunction and/or infection or volume overload. The incidence of complications increases with patient age and the severity of chronic obstructive pulmonary disease, as measured with pulmonary function testing (1204,1205). None of these studies, however, address the relative risks and benefits of CABG in subjects with chronic obstructive pulmonary disease, thereby precluding a specific recommendation regarding the performance of CABG in these patients. In preparation for CABG, optimizing pulmonary function is imperative (1206). An RCT of 279 patients (1199) showed that preoperative respiratory muscle training reduced postoperative pulmonary complications (including pneumonia) and length of stay in patients at high risk for such complications after CABG. Such muscle training is indicated in all patients before CABG, especially those with impaired baseline pulmonary function.

Two prospective RCTs have shown that prophylactic nasal continuous positive airway pressure after CABG improves pulmonary function and offers protection from postoperative pulmonary complications (1200,1201). However, the applicability of these results to patients with impaired pulmonary function is uncertain, because those with severe underlying lung disease and other comorbid conditions were not enrolled. Although noninvasive positive pressure ventilation may be useful in subjects with borderline pulmonary function postoperatively, its overuse should be avoided, because it may cause gastric distention, thereby increasing the risk of vomiting and aspiration. Improved lung function has been achieved with the use of high thoracic epidural anesthesia in patients undergoing CABG (36,37), but its application has been limited by concerns about paraspinal and epidural hemorrhage related to epidural catheter insertion.

Despite some evidence that oral corticosteroids improve pulmonary function after cardiac surgery (1207,1208), their use has not been adopted widely in subjects undergoing CABG. Finally, a consistent reduction in postoperative pulmonary complications has not been shown when off-pump (as opposed to on-pump) CABG is performed (1209).

6.6. Patients With End-Stage Renal Disease on Dialysis: Recommendations

CLASS IIb

1. CABG to improve survival rate may be reasonable in patients with end-stage renal disease undergoing CABG for left main coronary artery stenosis of greater than or equal to 50% (479). *(Level of Evidence: C)*
2. CABG to improve survival rate or to relieve angina despite GDMT may be reasonable for patients with end-stage renal disease with significant stenoses (≥70%) in 3 major vessels or in the proximal LAD artery plus 1 other major vessel, regardless of LV systolic function (1210). *(Level of Evidence: B)*

CLASS III: HARM

1. CABG should not be performed in patients with end-stage renal disease whose life expectancy is limited by noncardiac issues. *(Level of Evidence: C)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

Rates of cardiovascular morbidity and mortality are increased in patients with CKD compared with age-matched controls without CKD, and the magnitude of the increase is directly related to the severity of CKD. About half of those on maintenance dialysis die from a cardiovascular cause (476). At present, the prevalence of CKD in the general population of the United States is estimated to be 13%, with approximately 5.8% of these having Stage III–V disease (i.e., glomerular filtration rate <60 mL/min/1.73 m^2) (1211). In 2009, >525,000 Americans were receiving maintenance hemodialysis (1212).

To date, randomized comparisons of CABG and medical therapy in patients with CKD (irrespective of its severity) have not been reported. Observational studies have demonstrated an improved survival rate with CABG (compared with medical therapy) in patients with CKD and multivessel CAD (57,479). At the same time, these observational studies as well as other registries have demonstrated a markedly reduced long-term survival rate in patients with CKD undergoing CABG compared with nondialysis CABG patients (1213–1216), with the magnitude of the decrease directly related to the severity of CKD. In these reports, subjects with CKD undergoing CABG had an increased incidence of periprocedural complications, including mediastinitis, need for blood transfusion, prolonged ventilation, reoperation, stroke, and increased length of hospital stay (1210).

6.7. Patients With Concomitant Valvular Disease: Recommendations

CLASS I

1. Patients undergoing CABG who have at least moderate aortic stenosis should have concomitant aortic valve replacement (1217–1220). *(Level of Evidence: B)*
2. Patients undergoing CABG who have severe ischemic mitral valve regurgitation not likely to resolve with revascularization should have concomitant mitral valve repair or replacement at the time of CABG (1221–1226). *(Level of Evidence: B)*

CLASS IIa

1. In patients undergoing CABG who have moderate ischemic mitral valve regurgitation not likely to resolve with revascularization, concomitant mitral valve repair or replacement at the time of CABG is reasonable (1221–1226). *(Level of Evidence: B)*

CLASS IIb

1. Patients undergoing CABG who have mild aortic stenosis may be considered for concomitant aortic valve replacement when evidence (e.g., moderate–severe leaflet calcification) suggests that progression of the aortic stenosis may be rapid and the risk of the combined procedure is acceptable. *(Level of Evidence: C)*

6.8. Patients With Previous Cardiac Surgery: Recommendation

CLASS IIa

1. In patients with a patent LIMA to the LAD artery and ischemia in the distribution of the right or left circumflex coronary arteries, it is reasonable to recommend reoperative CABG to treat angina if GDMT has failed and the coronary stenoses are not amenable to PCI (380,1227). *(Level of Evidence: B)*

6.8.1. Indications for Repeat CABG

RCTs comparing medical therapy to CABG in subjects with SIHD demonstrated that those with specific angiographic findings, such as left main disease, 3-vessel disease, and 2-vessel disease that includes the proximal LAD artery, derive a survival benefit from CABG (318). At the same time, it is unknown if CABG provides a survival benefit compared with medical therapy in patients with these anatomic findings who have had previous CABG. It is logical to assume that subjects with previous CABG and these anatomic findings would, in fact, derive a survival benefit from repeat CABG provided that CABG could be performed with an acceptable risk. The importance of recurrent MI in the distribution of the LAD artery has been shown to be associated with a poor prognosis in patients with previous CABG. The long-term outcomes of 723 patients with diseased SVGs who did not undergo reoperation or PCI within 1 year of angiography were reviewed (1228). A stenosis of a graft to the LAD artery was associated with decreased rates of survival, reoperation-free survival, and event-free survival. On the basis of these data, these authors suggest that a >50% stenosis in a graft to the LAD artery is an indication for reoperation. In contrast, patients without ischemia in the LAD artery distribution do not derive a survival benefit from repeat CABG. In an observational study from the Cleveland Clinic, the survival rate of 4,640 patients with patent LIMA grafts to the LAD artery and ischemia in the distribution of the right and/or left circumflex arteries who were treated with repeat CABG, PCI, or medical therapy was examined (380). No improvement in survival was observed in either revascularization group compared with those treated medically.

6.8.2. Operative Risk

Because of the technical difficulty of repeat CABG and the high risk profiles of these patients, reoperative CABG is associated with higher rates of morbidity and mortality than is primary CABG (945,1229–1235). With advances in surgical techniques, some groups have reported a decline in mortality rate for patients undergoing repeat CABG (1233,1236). An observational study suggested that the higher operative risk with reoperation is related to the higher patient risk profiles and not to the technical challenges of the operation itself, thereby suggesting that improvements in surgical techniques have neutralized the risk associated with the complexity of repeat CABG (1233), but others continue to suggest that technical issues are still important in causing the higher mortality rate in these individuals.

6.8.3. Long-Term Outcomes

The survival rate after repeat CABG is lower than that after primary CABG. A multicenter study from Australia re-

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ported 1, 3, 5, and 6 year survival rates in reoperative CABG patients of 93.1%, 90.5%, 85.9%, and 80.5%, respectively (1235)—survival results that were significantly lower than those observed after primary CABG. However, after adjusting for differences in risk profiles between primary and reoperative CABG patients, no difference in long-term survival rate was apparent. The variables associated with decreased late survival rate included advanced age, hypertension, elevated serum cholesterol, diabetes mellitus, PAD, renal failure, left main CAD, LV systolic dysfunction, and emergency status (1235).

Compared with primary CABG, repeat CABG is less successful at relieving angina (1237,1238), although a 2004 quality-of-life analysis reported that repeat CABG was as effective as primary CABG in relieving angina and improving functional capacity and quality of life (1239).

6.9. Patients With Previous Stroke

Patients with a previous stroke or TIA are at higher risk for a perioperative stroke during CABG than those without such a history. A meta-analysis of the data from several studies observed a perioperative stroke risk of 8.5% in patients with previous stroke (compared with 2.2% in those without a previous neurological event) ($p<0.0001$) (860). When subjects with a history of stroke or TIA were analyzed separately (i.e., stroke only or TIA only), the increased perioperative risk in comparison with neurologically asymptomatic patients was present in both groups. In a multivariate logistic regression analysis of 16,194 cardiac surgery patients, a history of cerebrovascular disease was identified as an independent predictor of perioperative stroke (1240). The STS National Cardiac Surgery Database demonstrated an increased risk of perioperative death, perioperative stroke, and prolonged length of stay in patients with a history of stroke who underwent isolated CABG from 2002 to 2006 (308).

6.10. Patients With PAD

CAD and PAD, generally defined as atherosclerotic disease of the aorta, its visceral arterial branches (renal and mesenteric), and the arteries of the lower extremities, often coexist. The presence of PAD is an independent predictor of early (1241) and late death in CABG patients. In the STS National Cardiac Surgery Database, 774,881 patients underwent isolated CABG over a 5-year period, of whom 15.5% had PAD. The presence of PAD was an independent risk factor for in-hospital death or death within 30 days of CABG. In addition, PAD was an independent risk factor for perioperative stroke and subsequent need for post-CABG limb revascularization or amputation. Potential but unproven explanations for the adverse effects of PAD on long-term survival after CABG include: 1) The presence of PAD may lead to vascular events (i.e., cerebrovascular events) that adversely affect post-CABG survival; 2) PAD may be a marker for more severe CAD, which may lead to an increased rate of post-CABG death from cardiac causes despite revascularization; and 3) PAD may contribute to noncardiovascular death in the long term. Revascularization of PAD before CABG is not known to improve post-CABG outcomes.

7. Economic Issues

7.1. Cost-Effectiveness of CABG and PCI

In the United States, it is estimated that the annual hospital costs of CABG are approximately $10 billion (1242). Despite the increasing risk profile of CABG candidates, it nonetheless is becoming more cost-effective. Hospital charges from the Nationwide Inpatient Sample of nearly 5.5 million patients who had isolated CABG in the United States from 1988 to 2005 were examined (1243). A decrease in risk-adjusted mortality rate, from 6.2% to 2.1% ($p<0.0001$), was noted. When hospital costs were corrected for inflation, they declined from $26,210 in 1988 to $19,196 in 2005 ($1,988) ($p<0.0001$).

Several factors tend to increase the cost of CABG, including advanced patient age, female sex, African-American ethnicity, postoperative complications, longer hospital stay, and multiple comorbidities, particularly CKD (1244–1247). The National Health Service Foundation Trust in Britain found that patients >75 years of age undergoing CABG had higher rates of postoperative complications and greater resource utilization than their younger counterparts (1244). Similarly, the Maryland Health Services Cost Review Commission reported an increased total cost and length of hospital stay with increasing age in patients undergoing CABG (1245). The same phenomenon was not present with PCI until the patients were >80 years old. In an examination of data from 12,016 subjects undergoing CABG in New York State in 2003, it was determined that older age, female sex, and African-American ethnicity were associated with higher costs (1247). Clinical characteristics, such as a lower LVEF, number of diseased vessels, previous open-heart operations, and numerous comorbidities, further increased costs. Larger hospitals were associated with higher CABG discharge costs, whereas costs significantly decreased with higher CABG volumes.

Not surprisingly, perioperative complications lead to increased costs. An examination of the Medicare Provider Analysis and Review file of data from 114,223 Medicare beneficiaries who survived CABG in 2005 showed the mean cost of hospitalization associated with CABG to be $32,201 ± $23,059 for a mean length of stay of 9.9 ± 7.8 days. Those with complications (13.6% of patients) consumed significantly more hospital resources (incremental cost, $15,468) and had a longer length of stay (average additional stay, 1.3 days) (1246).

Evidence for the role of off-pump versus on-pump CABG in decreasing costs is conflicting. In a randomized study comparing off-pump and on-pump CABG, the mean total hospitalization cost per patient was $2,272 less for

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

off-pump CABG at hospital discharge and $1,955 less at 1 year (1248). Another study of 6,665 patients who underwent CABG between 1999 and 2005 determined that off-pump CABG provided a small short-term gain (1249), although off-pump patients had increased long-term risks of repeat revascularization and major vascular events, especially if they were considered to be high risk. In the long run, in fact, off-pump patients utilized more resources.

7.1.1. Cost-Effectiveness of CABG Versus PCI

Medical costs and quality of life were examined 10 to 12 years after patients were randomly assigned to receive angioplasty or CABG in the BARI trial (1250). Although CABG costs initially were 53% higher, the gap closed to <5% by the end of 2 years. After 12 years, the average cost was $123,000 in CABG patients and $120,000 for PCI patients. Cumulative costs were significantly higher among patients with diabetes mellitus, heart failure, and comorbid conditions, and they were higher in women. CABG was deemed to be as cost-effective as PCI in patients with multivessel CAD.

The cost of coronary artery revascularization in 6,218 patients with and without CKD whose data were available in the Duke database was examined (1251). CABG was an economically attractive alternative to PCI or medical therapy for all patients with left main or 3-vessel CAD without concomitant CKD as well as those with 2-vessel CAD with concomitant CKD. For subjects with 3-vessel CAD and concomitant CKD, 2-vessel CAD without CKD, and 1-vessel CAD regardless of renal function, medical therapy was an economically attractive strategy compared with CABG or PCI. This analysis concluded that CABG is most economically attractive compared with PCI and medical therapy in patients to whom it confers the greatest survival advantage and for whom the cost of alternative treatments is greatest (i.e., those with the most severe CAD). Although CABG was more expensive than medical therapy for all patients, the survival benefits associated with it were of such magnitude in some subjects that it was economically attractive.

The cost-effectiveness of CABG and PCI in high-risk patients was analyzed in the AWESOME (Angina With Extremely Serious Operative Mortality Evaluation) study (446), in which costs were assessed at 3 and 5 years. After 3 years, the average total cost was $63,896 for PCI and $84,364 for CABG, a difference of $20,468. After 5 years, the average total cost was $81,790 for PCI and $100,522 for CABG, a difference of $18,732. The authors concluded that PCI was less costly and at least as effective for urgent revascularization in high-risk patients with medically refractory angina.

7.1.2. CABG Versus PCI With DES

The use of DES for PCI will require a reassessment of cost-effectiveness. Although the initial procedure is considerably more expensive than the use of balloon angioplasty or BMS, equaling the cost of CABG in many patients with multivessel CAD, the cost of reintervention for restenosis may be reduced. The cost-effectiveness will depend on the pricing of stents, utilization rates of the more expensive stents, and efficacy. In a 2010 study from Japan comparing the total costs at 2 years of CABG and DES implantation in patients with left main CAD, the total costs were significantly lower for those undergoing CABG than for those receiving a DES (1252).

8. Future Research Directions

With improvements in percutaneous techniques and medical therapy, on-pump CABG and off-pump CABG will increasingly be reserved for patients with extensive CAD, many of whom have had previous PCI. The future of CABG will be directed at improving its results in high-risk patients and making CABG less invasive for elective revascularization. Minimally invasive techniques, with the use of robotics and anastomotic connectors, intraoperative imaging, hybrid procedures, and protein and gene therapy, appear promising. Robotic technology in minimally invasive CABG leads to less traumatic harvesting of the LIMA for minimally invasive direct coronary artery bypass procedures compared with nonrobotic techniques (1253). The ultimate goal of robotic CABG is totally endoscopic CABG, but its use has been limited, at least partly because of a substantial learning curve, cost considerations, and few data demonstrating noninferior graft patency and outcomes compared with standard CABG.

Anastomotic connectors may enable more routine application of totally endoscopic anastomoses in subjects undergoing minimally invasive CABG. Because hand-sewn anastomoses are technically challenging when performed endoscopically, consideration has been given to the concept of anatomic connectors to facilitate more reproducible and less technically demanding procedures and ultimately to allow widespread use. Both proximal and distal connectors may be used. Several options are being developed, some only available outside the United States, and the evidence base supporting their use is evolving (1254). The PAS-Port proximal device has been associated with acceptable outcomes. In two prospective studies, its angiographic graft patency 9 months after CABG was similar to that of hand-sewn anastomoses (1255,1256). With this device, the proximal anastomoses must be constructed before the distal ones. At present, only 1 distal device, the Cardica C-Port, has been approved for use in the United States. The prospective studies (1257,1258) demonstrated a 6-month overall patency of 96% in 102 subjects. These devices increase the cost of the operation.

Over the past 20 years, the patency rate of all graft types has improved gradually, so that the present failure rate of LIMA grafts at 1 year is about 8% and of SVGs roughly 20% (1259). Many patients being referred for CABG nowadays have far advanced CAD, which is often diffuse

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

and exhibits poor vessel runoff. Technical issues at the time of surgery may influence graft patency, and intraoperative imaging may help to delineate technical from nontechnical issues. Because coronary angiography is rarely available intraoperatively, other techniques have been developed to assess graft integrity at this time, most often the transit-time flow and intraoperative fluorescence imaging. The transit-time flow is a quantitative volume-flow technique that cannot define the severity of graft stenosis or discriminate between the influence of the graft conduit and the coronary arteriolar bed on the mean graft flow. Intraoperative fluorescence imaging, which is based on the fluorescent properties of indocyanine green, provides a "semiquantitative" assessment of graft patency with images that provide some details about the quality of coronary anastomoses (1260). Although both methods are valuable in assessing graft patency, neither is sufficiently sensitive or specific to allow identification of more subtle abnormalities (1260). It is hoped that such imaging may help to reduce the occurrence of technical errors.

The hybrid suite can be used as an operating room and a catheterization laboratory. It allows the performance of an angiogram after CABG so that one can identify abnormal grafts, providing the opportunity to revise them (with PCI or surgery) before leaving the operating room. Until completion angiography becomes more routine (in a hybrid suite), cardiac surgeons must rely on reasonably accurate, albeit imperfect, methods to identify problems with a recently implanted graft.

8.1. Hybrid CABG/PCI

Advances in surgical techniques and the introduction of DES have provided a platform for a "hybrid revascularization strategy" that combines grafting the LAD artery with the LIMA and stenting the non-LAD arteries with DES (instead of bypassing them with SVGs). Although preliminary data (1261) have indicated that a hybrid strategy may be a reasonable alternative in some patients with multivessel CAD, its real effect will not be known until results of RCTs are available (1261). The primary purpose of performing hybrid CABG is to decrease the morbidity rate of traditional CABG in high-risk patients. Although hybrid revascularization is most often performed in a staged fashion, a simultaneous hybrid procedure can be performed in a hybrid suite, offering several potential advantages, including improving the efficiency and cost-effectiveness of therapy as well as condensing therapy into 1 patient encounter. If a staged approach is chosen, minimally invasive CABG performed first, followed days later by PCI, is probably preferable, so as to enable surgery without the unwanted effects of antiplatelet therapy as well as to enable complete angiography of the LIMA graft at the time of PCI. The major disadvantage of this approach is that if complications occur with PCI, a third procedure may be necessary. Even with a hybrid suite, one of the most substantive barriers to simultaneous minimally invasive CABG and PCI is the management of antiplatelet therapy. The role of hybrid CABG–PCI compared with sole PCI and sole conventional CABG awaits the results of the ongoing observational study of hybrid coronary revascularization by the National Heart, Lung, and Blood Institute.

8.2. Protein and Gene Therapy

Several proteins, such as vascular endothelial growth factor, acidic fibroblast growth factor, and basic fibroblast growth factor, induce angiogenesis (1262); as a result, interest has grown in using these substances to stimulate myocardial perfusion. One RCT found that patients who were given 100 mcg of basic fibroblast growth factor became angina free, and nuclear perfusion testing appeared to show improved perfusion (1262). Another RCT has suggested that the intracoronary injection of high-dose angiogenic molecules yields improvement in symptoms, exercise time, functional capacity, and myocardial perfusion (1263). Alternatively, gene therapy may be used to induce angiogenesis, but conceptual concerns with intravascular gene therapy, such as peripheral uptake into nontarget tissues and subsequent unintended effects, have been raised.

8.3. Teaching CABG to the Next Generation: Use of Surgical Simulators

Over the past decade, pressure on hospitals and physicians to ensure high quality and safety has increased. Public reporting of outcomes, common in many states, has been endorsed by the STS. In addition, healthcare reform has placed great emphasis on the efficiency of care. These factors, coupled with the increased complexity of patients referred for CABG, the decreased number of qualified physicians specializing in cardiac surgery, and the restrictions on resident work hours, make the teaching of surgical techniques to the next generation a substantial challenge.

Given the success of simulator training of airline and military personnel, it has the potential to have a major impact on surgical training paradigms. With surgical simulators, a trainee's first distal anastomosis in an actual patient will occur only after mastering the technique on a simulator (1264). The mastery of basic skills will allow the trainee to focus on more complex tasks as well as to understand the conduct of the operation more thoroughly and quickly. The fundamentals of simulator training are based on the learning principle of "deliberate practice," in which an individual practices a finite task until it is mastered. Still, before this method of training can be incorporated into a formal curriculum, several issues must be addressed. Trainees must have adequate supervision and instruction to ensure appropriate technique, which will require that attending surgeons have time away from clinical and academic duties to provide simulator training. This poses a considerable challenge under current reimbursement requirements, and a reimbursement system that provides an incentive to active surgeons to teach residents in the simulation laboratory will be required. As an alternative,

training programs may opt to hire recently retired surgeons to teach in the simulation laboratory. Finally, simulators must become more robust, with perhaps computer-enhanced clinical scenarios, before the residents who train on them are qualified to care for patients.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$10,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACCF/AHA, a person has a *relevant* relationship IF: (a) The *relationship or interest* relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the *document*; or (b) the *company/entity* (with whom the relationship exists) makes a drug, drug class, or device addressed in the *document*, or makes a competing drug or device addressed in the *document*; or (c) the *person or a member of the person's household*, has a reasonable potential for financial, professional or other personal gain or loss as a result of the issues/content addressed in the *document*. *Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply. †No financial benefit. ‡Significant relationship.

AVR indicates aortic valve replacement; CABG, coronary artery bypass graft surgery; and IABP, intraaortic balloon pump.

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review and determined to be relevant. It does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$10,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review.

According to the ACCF/AHA, a person has a *relevant* relationship IF: (a) The *relationship or interest* relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the *document*; or (b) the *company/entity* (with whom the relationship exists) makes a drug, drug class, or device addressed in the *document*, or makes a competing drug or device addressed in the *document*; or (c) the *person or a member of the person's household*, has a reasonable potential for financial, professional or other personal gain or loss as a result of the issues/content addressed in the *document*.

*No financial benefit. †Significant relationship.

AATS indicates American Association for Thoracic Surgery; ACCF, American College of Cardiology Foundation; AHA, American Heart Association; CABG, coronary artery bypass graft surgery; PCI, percutaneous coronary intervention; SCA, Society of Cardiovascular Anesthesiologists; STEMI, ST-elevation myocardial infarction; and STS, Society of Thoracic Surgeons.

APPENDIX 3. ABBREVIATION LIST

ACE = angiotensin-converting enzyme
ACS = acute coronary syndrome
AF = atrial fibrillation
AKI = acute kidney injury
ARB = angiotensin-receptor blockers
BMS = bare-metal stent
CABG = coronary artery bypass graft surgery
CAD = coronary artery disease
CKD = chronic kidney disease
CPB = cardiopulmonary bypass
DAPT = dual antiplatelet therapy
DES = drug-eluting stent
EF = ejection fraction
GDMT = guideline–directed medical therapy
ICU = intensive care unit
IMA = internal mammary artery
LAD = left anterior descending
LDL = low-density lipoprotein
LIMA = left internal mammary artery
LV = left ventricular
LVEF = left ventricular ejection fraction
MACE = major adverse coronary events
MI = myocardial infarction
NSTEMI = non–ST-elevation myocardial infarction
PAC = pulmonary artery catheter
PAD = peripheral artery disease
PCI = percutaneous coronary intervention
RCT = randomized controlled trial
SIHD = stable ischemic heart disease
SIRS = systemic inflammatory response system
STEMI = ST-elevation myocardial infarction
SVG = saphenous vein graft
TEE = transesophageal echocardiography
TIA = transient ischemic attack
TMR = transmyocardial laser revascularization
UA = unstable angina

EDITORIAL COMMENT

Antiplatelet Therapy and Coronary Artery Bypass Graft Surgery

A Fallow Land*

Gilles Montalescot, MD, PHD,
Jean-Sébastien Hulot, MD,
Jean-Philippe Collet, MD, PHD

Paris, France

Despite many advances, open heart surgery is still associated with the risks of bleeding and thrombotic events. Whether to continue antiplatelet therapy during surgery is often handled differently by different institutions, with little interpatient variability within an institution. This confusion is caused by the lack of scientific evidence, so that decisions are being based on individual or local experience, somewhat oriented by recommendations, but based mainly on expert opinion.

See page 1994

Interruption of antiplatelet therapy (APT). In coronary patients on single oral APT, discontinuation of APT, usually aspirin, exposes them to an increased risk of death (1). In stented coronary patients, discontinuation of APT, especially if done prematurely and/or when interruption concerns both antiplatelet agents, exposes them to an increased risk of stent thrombosis and mortality. Therefore, current guidelines have warned against premature and unjustified discontinuation of APT in coronary patients (2).

In contrast, coronary patients on APT undergoing coronary artery bypass graft (CABG) surgery are exposed to an excess of bleeding complications. Bleeding complications and transfusions have been associated with an excess of ischemic complications and mortality, at both short- and long-term follow-up (3,4). Therefore, current guidelines have increased physicians' awareness of the issue and proposed strategies to reduce the risk of bleeding. Concerning clopidogrel, it is currently recommended to stop treatment 5 to 7 days before CABG surgery on the basis of pharmacodynamic studies and a post hoc analysis of a large randomized trial in acute coronary syndrome (4). Background aspirin therapy is nowadays accepted for CABG surgery, although it was not the case many years ago. Concerns about bleeding were such that it resulted in the preoperative discontinuation of aspirin therapy until aspirin was shown to reduce mortality in CABG surgery (5).

Several reports have suggested that the bleeding risk could be kept under control during CABG surgery even with continuation of dual APT (6,7). Such a strategy would of course have the advantage of not exposing patients to recurrent ischemic events while withholding thienopyridine treatment and not postponing surgery for the only reason of active APT. Moreover, several reports have suggested in the past that APT may improve the post-operative outcome of patients undergoing CABG surgery. Aspirin prevented early post-operative graft occlusion and reduced mortality (5) and glycoprotein IIb/IIIa inhibitors were shown to reduce death or myocardial infarction in CABG patients when compared with placebo (8). Platelet consumption and dysfunction after cardiopulmonary bypass has been widely described with similarities to what was described for hemodialysis. Interestingly, both ticlopidin and clopidogrel have been shown to reduce the frequency of thrombosis of arteriovenous fistulae in patients undergoing hemodialysis (9,10). Recently, patients undergoing CABG surgery who were taking prasugrel, a thienopyridine more potent than clopidogrel, had a large excess of major bleeding complications compared with those taking clopidogrel (11.3% vs. 3.6%) in the randomized, double-blind TRITON (TRial to assess Improvement in Therapeutic Outcomes by Optimizing platelet inhibitioN) trial (11). However, mortality rates after CABG surgery tended to be lower in the prasugrel-treated patients than in the clopidogrel-treated patients. This disconnect between bleeding complications and mortality was further observed in the PLATO (PLATelet Inhibition and Patient Outcomes)-CABG study, which found a significant reduction of mortality with ticagrelor, a stronger $P2Y_{12}$ antagonist than clopidogrel, whereas bleeding and ischemic event rates were similar with clopidogrel and ticagrelor (12). These post hoc analyses have many biases, and the recommendations in both studies were to

From the Institut de Cardiologie, Hôpital Pitié-Salpêtrière, Paris, France. Dr. Montalescot has received research grants (to the institution) from Abbott Vascular, Bristol-Myers Squibb, Sanofi-Aventis, Eli Lilly, Guerbet Medical, Medtronic, Boston Scientific, Cordis, Stago, Centocor, Fondation de France, INSERM, Fédération Française de Cardiologie, Société Française de Cardiologie, ITC Edison, and Pfizer; and consulting or lecture fees from Abbott Vascular, Accumetrics, AstraZeneca, Bayer, Boehringer-Ingelheim, Bristol-Myers Squibb, Cordis, Daiichi-Sankyo, Eisai, Eli Lilly, GlaxoSmithKline, Menarini, Merck Sharpe & Dohme, Novartis, Pfizer, Portola, Sanofi-Aventis, Schering-Plough, and The Medicines Company. Dr. Hulot has received research grants from Fondation de France, MedCo, and INSERM; and consulting fees from Sanofi-Aventis, MedCo, and Eli Lilly. Dr. Collet has received a research grant (to the institution) from AstraZeneca, Bristol-Myers Squibb, Sanofi-Aventis, Eli Lilly, Guerbet Medical, Medtronic, Boston Scientific, Cordis, Stago, Fondation de France, INSERM, Fédération Française de Cardiologie, and Société Française de Cardiologie; has served as a consultant (receiving honoraria for past 2 years for consulting fees) to Sanofi-Aventis, Eli Lilly, and Bristol-Myers Squibb; and has received lecture fees from Bristol-Myers Squibb, Sanofi-Aventis, and Eli Lilly.

withhold APT for CABG surgery, which was of course difficult to control, leaving uncertainty as to the degree of platelet inhibition or recovery of platelet function at the time of surgery. Altogether, the literature on antiplatelet agents suggests that there may be an ischemic and/or mortality benefit with some degree of platelet inhibition in patients undergoing CABG surgery despite a possible risk of excess bleeding. The optimal degree of platelet inhibition for the best post-CABG risk/benefit ratio remains entirely unknown.

Controlling platelet activity for CABG surgery. Would information on residual platelet activity at the time of CABG surgery help identify patients at risk of further ischemic or bleeding complications? Is clopidogrel titration possible to maintain patient platelet reactivity in a predefined "optimal surgery window?" In this issue of the *Journal*, Kwak et al. (13) explore the relationship between platelet function after clopidogrel discontinuation and periprocedure blood loss. They correlated residual platelet reactivity before surgery and blood loss in 100 patients who interrupted clopidogrel before off-pump coronary artery bypass graft (OPCABG). The model of OPCABG allows accurate measurements of blood loss and limits post-operative thrombocytopenia and platelet dysfunction more frequently seen with cardiopulmonary bypass. They used the thromboelastography (TEG) platelet mapping assay (Ańemoscope Corp., Niles, Illinois) that measures platelet activation on the basis of blood coagulation and clot strength. It correlates with bleeding and may be used to guide transfusion after cardiac surgery but is not currently recommended for this indication (4). Limited data suggest that it can also identify patients at increased risk of ischemic events (14). The authors found that a persistent high level of platelet inhibition, as measured with the TEG platelet mapping assay at the time of surgery, was associated with a higher volume of blood loss irrespective of the delay between clopidogrel discontinuation and surgery. This finding suggests that recommendations of an average delay of discontinuation of APT before surgery (i.e., 5 days for clopidogrel) is not appropriate at the individual level. This is in line with what we know of the interindividual variability of response to clopidogrel, an inactive pro-drug that requires hepatic conversion into an active metabolite that binds to the platelet $P2Y_{12}$ receptor. The limits of the therapeutic window of platelet inhibition are still uncertain for percutaneous coronary intervention and unknown for CABG (Fig. 1).

What this study does not say is even more important than what it does say, and it should stimulate further studies. Is this test the best tool to identify the potential bleeders during or after surgery? Is the cutoff value of 70% obtained with the TEG platelet mapping assay the ideal threshold for the risk of bleeding? Is this value the same for on-pump surgery? How does it correlate with established point of care assays that have been used in clinical outcome studies performed in stented patients? Is there another threshold for the risk of ischemic events, and shall we now define an optimal surgery window for platelet reactivity to operate on patients (Fig. 1)? Can we improve the prognosis of CABG patients by a systematic monitoring of platelet function and operate when they reach such a predefined window of platelet reactivity?

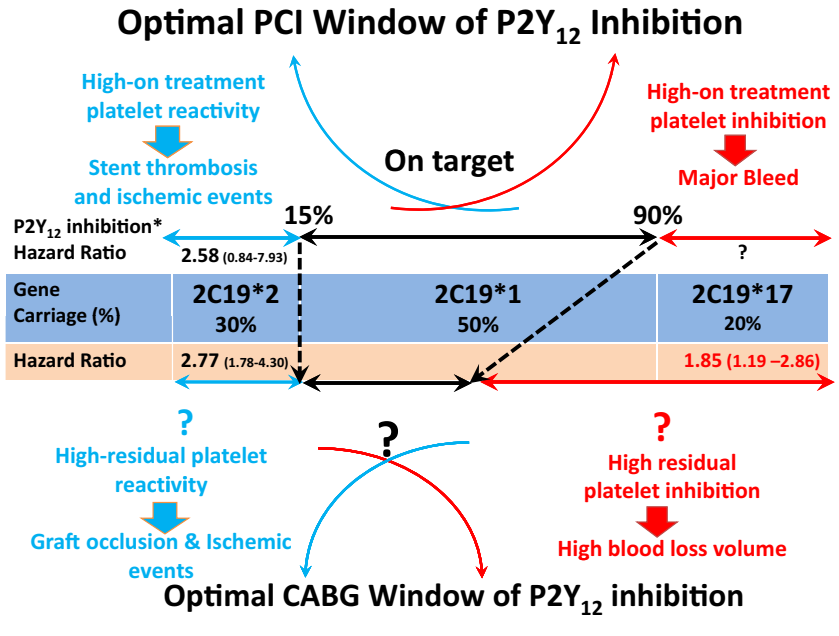

Figure 1 Optimal Window of Platelet Inhibition for PCI or CABG

Is there an optimal window of $P2Y_{12}$ inhibition for percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG) patients? Is the therapeutic window different? *% inhibition with VerifyNow.

A call for studies in CABG patients. Several randomized trials (NCT00661206, NCT00780156, NCT00977938, NCT00822536, and NCT00640679), totaling >35,000 patients, are evaluating the safety and efficacy of thienopyridine interruption after stenting to try to determine the best timing of discontinuation. Not a single randomized study has evaluated the safety and efficacy of clopidogrel interruption before CABG surgery. Despite the huge gap in knowledge and the lessons learned with aspirin, guidelines have validated the concept of clopidogrel interruption and provided the timelines for its withdrawal before surgery. This uncharted territory extends to the post-operative period in which similar uncertainties exist about the use of thienopyridines in patients with or without pre-operative acute coronary syndromes.

The new tools and the new drugs may help to clarify the path to better understanding and better management of these patients. The bedside assays to monitor platelet function may stimulate descriptive studies on what is currently performed and what could be new approaches in the pre-operative phase.

Bedside genetic testing is also an interesting way to predict on-treatment platelet reactivity and off-treatment residual platelet inhibition and thus anticipate perioperative bleeding and ischemic events. Although several studies have now clearly established the increased risk of ischemic events in carriers of the loss-of-function CYP2C19*2 genetic variant, recent evidence suggests that the gain-of-function CYP2C19*17 genetic variant is associated with an increased bleeding risk in clopidogrel-treated patients (Fig. 1). Whether the delay in clopidogrel discontinuation should be individualized according to the genetic profile requires further investigations. Rapid genetic testing is around the corner and using this information may improve the predictability of platelet function assays.

New drugs, such as cangrelor, an intravenous potent, reversible, and specific $P2Y_{12}$ purine receptor antagonist that blocks adenosine diphosphate–induced platelet activation and aggregation, will clarify management of these patients in the BRIDGE (Maintenance of Platelet Inhibition With Cangrelor) trial. In this randomized, double-blind study, patients scheduled for CABG surgery will receive from the day of clopidogrel interruption a cangrelor (or placebo) infusion to maintain levels of inhibition at least equivalent to those expected to be maintained if a thienopyridine (clopidogrel or ticlopidine) had not been discontinued, using the bedside VerifyNow $P2Y_{12}$ assay. The infusion will be discontinued 1 to 2 h before surgery, with the aim being to show that patients can undergo surgery without excessive bleeding perioperatively. Other reversible intravenous agents are being developed and may well fit the perioperative management of platelet reactivity in patients undergoing CABG surgery, possibly with simultaneous platelet function monitoring at the bedside.

We need to realize that the risk of bleeding associated with CABG surgery does not obviate the need for clinical trials evaluating other hard end points. A series of small studies, such as the one reported by Kwak et al. (13), could collectively draw awareness and lead to rigorous exploration of the platelet issues linked to CABG indication. The new diagnostic tools and the new drugs may help to generate concerted scientific action with anesthetists and cardiac surgeons.

Coronary Revascularization in Context

Richard A. Lange, M.D., and L. David Hillis, M.D.

Coronary-artery bypass grafting (CABG), introduced in 1968, was the only method of coronary revascularization until 1977, when percutaneous balloon angioplasty was first performed. The complications of balloon angioplasty (acute vessel closure in 3 to 5% of patients and restenosis in almost half) prevented its use in patients with severe coronary artery disease. In the 1990s, the introduction of bare-metal stents led to reduced rates of these complications. The improved short-term and long-term procedural success with percutaneous coronary intervention (PCI) allowed for its safe and effective performance in patients with severe coronary artery disease. By the year 2000, more PCI procedures than CABG procedures were being performed in the United States. In early 2000, drug-eluting stents were approved for use in Europe and North America, after studies showed a markedly reduced incidence of restenosis with drug-eluting stents as compared with bare-metal stents. Subsequently, the use of drug-eluting stents was rapidly adopted; in 2006, a total of 253,000 CABG procedures and 1,131,000 PCI procedures were performed in the United States,[1] with drug-eluting stents used in 90% of the PCIs.[2]

Do CABG and PCI result in similar outcomes? A recent review[3] of 23 randomized, controlled comparisons of CABG and PCI (by means of balloon angioplasty or bare-metal stenting) in approximately 10,000 patients showed that CABG was superior to PCI in relieving angina and averting repeat revascularization procedures. The rates of survival at 1, 5, and 10 years were similar for the two procedures, even though CABG carried a higher risk of stroke (1.2%, vs. 0.6% with PCI). However, most of the 23 studies did not involve patients with severe coronary artery disease (i.e., left main or three-vessel coronary artery disease) and did not use the latest revascularization techniques.

In this issue of the *Journal*, Serruys et al. describe the Synergy between PCI with Taxus and Cardiac Surgery (SYNTAX) trial[4] (ClinicalTrials.gov number, NCT00114972), in which 1800 patients with left main or three-vessel coronary artery disease were randomly assigned to undergo CABG or PCI (with drug-eluting stents) to determine which was the better revascularization strategy. Previously published studies comparing the two procedures in such patients were single-center, nonrandomized trials with relatively small numbers of patients, and the results were inconsistent: some[5] showed that CABG was associated with fewer major adverse events, whereas others[6-8] showed that the outcomes with CABG and with PCI were similar.

In the SYNTAX trial, patients treated with PCI involving drug-eluting stents were more likely than those undergoing CABG to reach the primary end point of the study — death from any cause, stroke, myocardial infarction, or repeat revascularization — within 12 months after randomization (17.8% of patients vs. 12.4%). In an analysis of secondary end points, the two treatment groups had similar rates of death from any cause, stroke, or myocardial infarction (7.6% for PCI and 7.7% for CABG). Patients undergoing PCI were more likely than those undergoing CABG to require repeat revascularization (13.5% vs. 5.9%) but were less likely to have a stroke (0.6% vs. 2.2%). The investigators do not discuss whether the strokes were related to the procedure or whether the risk of having a stroke was influenced by differences between the two groups in the occurrence of atrial fibrillation, use of aspirin or other antiplatelet agents, or presence of risk factors for atherosclerosis.

The study has several notable strengths. First, it was a prospective, multicenter trial in which a large number of patients were enrolled at 85 centers in Europe and the United States. Second, it attempted to include "all comers" with left main or three-vessel coronary artery disease. In contrast to previously published comparisons of PCI and CABG, in which only about 10% of screened patients were included, the enrollment rate in the SYNTAX trial was impressively high, with 71% of screened patients enrolled in the randomized or registry cohorts. Third, the study used state-of-the-art CABG and PCI (with arterial grafts and drug-eluting stents, respectively), both with excellent results. Fourth, a "heart team" consisting of an interventional cardiologist and cardiac surgeon reviewed each subject's data (including findings on coronary angiography), after which they reached agreement on which procedure or procedures should be offered to that subject.

The study also has limitations. First and most important, the follow-up period was only 12 months; the outcomes of PCI and CABG over a longer period of follow-up in patients with severe coronary artery disease are unknown. Second, since most of the patients (78%) were men, it is unknown whether these findings are applicable to women. Third, the patients who underwent CABG were less likely to receive optimal medical therapy (i.e., statins, aspirin or other antiplatelet agents, and angiotensin-converting–enzyme [ACE] inhibitors or angiotensin II–receptor antagonists), which may have contributed to their increased risk of stroke.

How should revascularization be accomplished in a patient with left main or three-vessel coronary artery disease? All pertinent data, including that from diagnostic angiography, should be reviewed by a cardiac surgeon and interventional cardiologist to determine the likelihood of safe and effective revascularization with PCI and with CABG. To ensure this kind of thorough review, coronary revascularization should not be performed at the time of diagnostic angiography, thereby allowing the heart team sufficient time to review all the data, reach a consensus, and discuss the findings with the patient. In the SYNTAX trial, the time from diagnostic angiography to revascularization averaged 6.9 days in the PCI group and 17.4 days in the CABG group.

An occasional patient is unable or unwilling to take dual antiplatelet agents (aspirin and clopidogrel), which are necessary after placement of a drug-eluting stent. In others, complete revascularization can be accomplished much more effectively with CABG than with PCI. Approximately one third of the patients in the SYNTAX study had one of these two issues. Such patients should be encouraged to undergo CABG. Conversely, patients with serious coexisting conditions or vessels unsuitable for grafting (about 5% of patients in the SYNTAX study) are poor candidates for CABG; they should be encouraged to undergo PCI.

If safe and complete revascularization is feasible with either PCI or CABG — as was true in roughly 60% of the patients in the SYNTAX study — an assessment of coronary anatomical characteristics should be performed, and a SYNTAX score assigned.[9,10] The presence of complex coronary anatomical features (assigned a high SYNTAX score) identifies patients with an increased risk of a suboptimal outcome with PCI; they should be encouraged to undergo CABG. Conversely, patients with less complex coronary anatomical features (i.e., a low SYNTAX score) should be presented with the advantages and disadvantages of each procedure and allowed to choose between them. Irrespective of which procedure is performed, the patient should receive optimal medical therapy involving an antiplatelet agent (or agents), a statin, and an ACE inhibitor, if appropriate.

The NEW ENGLAND JOURNAL of MEDICINE

Perspective Roundtable: CABG vs. Stenting: Clinical Implications of the SYNTAX Trial.

DR. THOMAS LEE: Welcome to a Perspective Roundtable of the *New England Journal of Medicine*. I'm Tom Lee, an associate editor of the *Journal*. And today I'll be here with two of my colleagues, discussing a trial that's just being released at the *Journal*'s Web site, the SYNTAX trial, which compares the impact of coronary-artery bypass graft surgery and percutaneous coronary intervention in patients with severe coronary disease.

On my right is Dr. David Hillis, chairman of medicine at the University of Texas Health Science Center at San Antonio. And on my left is Dr. Elizabeth Nabel, who's director of the National Heart, Lung and Blood Institute. Welcome to our Perspective Roundtable. And thank you for your insights today. Dave, why don't we start with you. And can you give our viewers a high level summary of the trial and the key results?

DR. DAVID HILLIS: This was an international, multicenter, randomized, controlled comparison of bypass surgery, CABG, versus PCI with drug-eluting stents in 1800 patients, all of them with left main or three-vessel coronary artery disease. They were randomized, as I mentioned, to one of those two therapies. They were then followed for one year, 12 months. And during that 12 months, the authors looked for an adverse event. Adverse events were defined as one of four: number one, all cause death; number two, myocardial infarction; number three, stroke; and number four, repeat revascularization. So, it was a combined end point of any one of those four events occurring within 12 months of randomization.

The main bottom-line results of the study was that, at one year, about 12% of the CABG patients had had one of these four adverse events. In contrast, 18% of the PCI patients had had one of those adverse events. So the bottom line conclusion of the authors was that CABG remains the standard of care for patients with left main and three-vessel coronary artery disease.

DR. LEE: Well, for people who just read the last couple lines of an abstract, that would be the message they walk away with, is that CABG seems to be the better approach. But it's more complicated than that. And Betsy, why don't you help us pick apart the outcomes that are used in this trial a little bit more.

DR. ELIZABETH NABEL: If we look at the primary end point, which Dr. Hillis articulated was a combination of death, MI, stroke and the need for revascularization, if we drill down further, there was no difference between the two groups in death, MI, and stroke at one year. The primary end point was really driven by an increased need for revascularization in the PCI group. So that is an important distinction that we must remember. Furthermore, if we look at the complication rate, there was a 1.6% higher incidence of stroke in the CABG group, compared to the PCI group.

Downloaded from www.nejm.org at DUKE MEDICAL CENTER LIBRARY on February 23, 2009 .

DR. LEE: Dave, I'm going to ask you, make that argument that CABG is the standard of care, the first choice for patients with severe coronary disease.

DR. HILLIS: Tom, I think that for patients with left main and three-vessel disease, CABG is certainly still the treatment of choice. The more complex the coronary anatomy — that is, the higher the SYNTAX score — the better the patients did with CABG as opposed to PCI. If the SYNTAX score was low, the two therapies seemed similar to one another.

Now secondly, I think it is important that patients who undergo CABG be treated with intensive medical therapy. One of the reasons that the stroke rate may have been higher in the CABG patients than in those randomized for PCI, was that the CABG patients were not treated as intensively with platelet inhibitors, ace inhibitors, and statins. So, if the patients go to surgery, one should not neglect their medical therapy.

DR. LEE: And Betsy, the case for thinking first about coronary intervention?

DR. NABEL: I think that there are patients who have complex coronary anatomy who would prefer to undergo PCI. They would prefer to accept the possibility of requiring a repeat revascularization, but do not want to subject themselves to an increased risk for stroke or to an increased recovery time that might occur from a sternotomy. So in this case, cost and quality of life might be important issues that would sway them towards preferring PCI.

DR. LEE: So, in the real world currently, I guess one reason why a lot of patients are getting the strategy not recommended by the conclusion, that is, going right to angioplasty, is the decisions are being made while the patient is lying on the table. But, in this case, there was time to step back and weigh both.

DR. HILLIS: Absolutely. I think it's an important point of the study, and that is, that what they referred to as a — quote, unquote — heart team sat down and, in a very detailed fashion, did a complete and thorough evaluation of each patient, including the patient's angiogram, after — and this team was composed of a cardiac surgeon and an interventional cardiologist. And they came to a consensus agreement on which of the two therapies would be better for that individual patient. In other words, the intervention was not done at the same time, or linked closely in time to the angiogram.

DR. LEE: Now Betsy, this trial was not funded by the NHLBI. This trial was funded by a manufacturer of drug-eluting stents. So one of the first things that a lot of readers do is look — could that have influenced the design of the trial in any way? What's your comment on that?

DR. NABEL: I think two points are salient, Tom. First is the trial design actually stacked the cards against the PCI intervention by combining both the hard end points of death, MI, and stroke, and the soft end point, the need for revascularization, into a combined primary end point. If the trial design had separated those end points, the primary end

Downloaded from www.nejm.org at DUKE MEDICAL CENTER LIBRARY on February 23, 2009 .
Copyright © 2009 Massachusetts Medical Society. All rights reserved.

point would have been equivalent, and there would have been a difference in the secondary end point. So, in other words, the device manufacturer, in some ways, stacked the cards against themselves.

But the second important point is this study is an example of comparative effectiveness research, which is receiving a lot of attention in Washington, DC, these days. Comparative effectiveness research is a rigorous evaluation of two different types of treatments or two different approaches towards the same medical condition and evaluates the effectiveness of both of those approaches. We're going to see much more research in this area coming down the pike. But I think the industry is to be congratulated for conducting this type of heads-on comparison in the manner in which they did.

DR. LEE: The pro-angioplasty approach points out the 1.6% higher stroke rate in bypass surgery. But when you really started looking carefully at, you know, Table 3 of the paper, which has the outcomes in some detail, the cardiac mortality is 1.6% higher in the angioplasty group than the bypass group. The total mortalities are similar, but the cardiac mortality is higher. Your comments on that?

DR. NABEL: Well, I think it's an interesting debate, Tom. On the one hand, CABG led to more complete revascularization with a higher stroke rate and, I'd also point out, a higher noncardiac mortality rate. On the other hand, we know PCI leads to less complete revascularization, perhaps a numerical difference in cardiac mortality, but a smaller stroke rate, and certainly easier on the individual, in terms of procedure recovery time and other factors.

I think subsequent studies will be looking at greater detail the differences between these groups and these factors, looking at cost-effectiveness, as well as quality-of-life issues. It may be that we're really — what we're coming down to, Tom, is a discussion between the patient and the medical and surgical team, really focusing on patient preferences, complexity of coronary anatomy, and potential risks and benefits, depending upon their medical state and their comorbidities.

DR. LEE: Well Betsy, there are a lot of unanswered questions, clearly. And you probably have as good or better insight than anyone in the country about what's coming, in the way of new trials to address those questions. So your summary of the big questions that need to be answered, and the trials that might answer them for us?

DR. NABEL: The NHLBI is now sponsoring the Freedom trial, which is a head-on comparison in diabetic patients between CABG and PCI. In this study, the primary end point will be the hard clinical end points of death, MI, and stroke. And need for revascularization will be a secondary end point. There will be intricate neurological assessments at various times along the study, so that we can get not only the stroke rate, but more subtle cognitive effects that might occur as the result of CABG or PCI.

In addition, we'll be looking at cost-effectiveness and quality-of-life measures in patients receiving both therapies. And finally, we'll have a 4-year follow-up period, so that we'll be able to see the outcomes over a longer period of time. So again, we need to understand, particularly in diabetic patients, whether CABG versus PCI achieves improved clinical outcomes.

DR. LEE: Well, you know, the issues are complicated. Medicine's complicated. And I think that patients should have a chance to articulate their preferences and weigh the risk of stroke versus risk of other kinds of outcomes. The SYNTAX trial will surely make those discussions much more informed and probably make them happen much more reliably. And I want to thank you two for your comments, because I think that they will help guide many of our audience members in those discussions. Thanks very much.

Context Clinical trials that have excluded patients at high risk for cardiac events have led to commercial labeling approval of drug-eluting stents; nevertheless, such high-risk patients commonly undergo stent placement in clinical practice. The degree to which they experience cardiac events at a higher rate than non–high-risk patients is unclear.

Objective To assess the rates of major adverse cardiac events during the index admission and 1 year after the implantation of drug-eluting stents in patients with high-risk angiographic and clinical features.

Design, Setting, and Patients From July 2004 to September 2005, consecutive patients who underwent attempted stent placement at 42 different hospitals throughout the United States were enrolled in a prospective multicenter registry. We analyzed outcomes of 3323 patients who received at least 1 drug-eluting stent for a reason other than acute ST-segment elevation myocardial infarction. The study population was divided into 2 groups based on presence of at least 1 of 9 off-label characteristics based on the current US Food and Drug Administration–approved indications for sirolimus- and paclitaxel-eluting stents.

Main Outcome Measures The composite clinical outcomes of death, myocardial infarction, or target vessel revascularization during the index admission and death, myocardial infarction, or target lesion revascularization at 1 year were evaluated.

Results Of the 3323 patients, 1817 (54.7%) had at least 1 off-label characteristic. During the index hospitalization, the composite clinical outcome occurred in 198 (10.9%) of patients in the off-label group and 76 (5.0%) of patients in the on-label group (adjusted odds ratio, 2.32; 95% confidence interval [CI], 1.75-3.07; $P<.001$). At 1 year, the composite clinical outcome occurred more often in the off-label group compared with the on-label group; 309 (17.5%) vs 131 (8.9%) (adjusted hazard ratio [HR], 2.16; 95% CI, 1.74-2.67; $P<.001$). Stent thrombosis also occurred more frequently among patients in the off-label group during the initial hospitalization (8 [0.4%] vs 0) and at 1 year: 29 (1.6%) vs 13 (0.9%), adjusted HR, 2.29 (95% CI, 1.02-5.16; $P=.05$).

Conclusions Compared with on-label use, off-label use of drug-eluting stents is associated with a higher rate of adverse outcomes during the index admission and at 1 year. Stent thrombosis occurred predominantly in patients who underwent off-label drug-eluting stent implantation. Clinicians should be cautious about extrapolating the benefits of drug-eluting stents over bare-metal stents observed in randomized clinical trials to higher-risk clinical settings that have not been assessed.

JAMA. 2007;297:2001-2009 www.jama.com

After the US Food and Drug Administration (FDA) approval of the sirolimus-eluting stent in April 2003[1] and the paclitaxel-eluting stent in March 2004,[2] drug-eluting stents have been used in the vast majority of percutaneous coronary interventions (PCIs) in the United States. FDA approval for commercialization was based on data from several randomized controlled trials demonstrating reductions of in-stent restenosis and target vessel revascularization among patients receiving drug-eluting stents.[3,4] Between April 2003 and December 2004, the proportion of procedures using drug-eluting stents increased from 19.7% to 78.2% in the United States.[5]

Common clinical situations generally associated with above-average risk were excluded from the original pivotal trials of drug-eluting vs bare-metal stents. Consequently, the original FDA label-approved indications for sirolimus-eluting stents were de novo lesions no longer than 30 mm in native coronary arteries with reference vessel diameters of at least 2.5 mm to at most 3.5 mm[1] and for paclitaxel-eluting stents de novo lesions no longer than 28 mm in native coronary arteries at least 2.5 to at most 3.75 mm in diameter.[2] In view of the widespread use of drug-eluting stents, however, several important questions are still un-

answered concerning their efficacy and safety in broader clinical practice.

The EVENT (Evaluation of Drug Eluting Stents and Ischemic Events) registry was launched shortly after original approval of drug-eluting stents and is a collaborative effort to assess the contemporary practice of stenting by performing a prospective evaluation of unselected patients undergoing implantation of an approved intracoronary stent in more than 40 centers (74% academic, median PCI volume 1400/y) in the United States.[6] To test the hypothesis that off-label use of these stents is associated with higher rates of cardiac events than approved (on-label) use, we assessed the frequency of off-label drug-eluting stent implantation and compared the rates of adverse clinical and procedural outcomes in patients undergoing on-label vs off-label implantation within the EVENT registry.

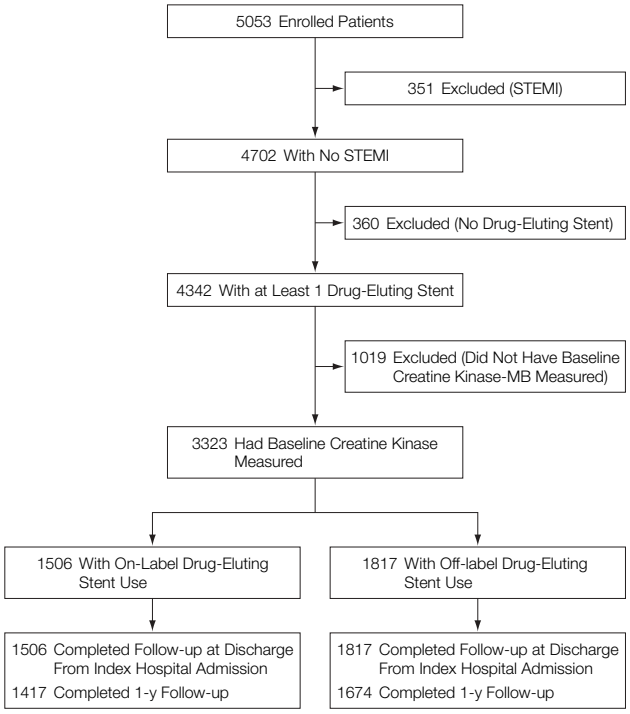
Table 1. Frequency of Off-Label Criteria*

Criteria for Off-Label Use	No. (%) of Patients (n = 1817)
>1 Lesion treated	1073 (59.1)
Total stent length ≥36 mm	975 (53.7)
Bifurcation lesion	473 (26.0)
Lesion in coronary artery bypass graft surgery	173 (9.5)
Baseline creatine kinase-MB >3 ULN	118 (6.5)
Stenosis preprocedure, 100%	112 (6.2)
Maximum balloon diameter >4 mm	76 (4.2)
Ejection fraction <25%	77 (4.2)
Unprotected LM intervention	20 (1.1)

Abbreviations: LM, left main coronary artery; ULN, upper limit of normal.
*Criteria are not mutually exclusive.

METHODS

The methods and population of EVENT have been described.[6] Patients undergoing attempted implantation of an approved intracoronary stent were eligible; enrollment of consecutive patients was strongly encouraged using previously enumerated strategies. The current analysis includes patients enrolled in the first 2 waves of the registry. Data about patient characteristics, presentation, and treatment were collected prospectively on standardized case report forms and submitted to the data coordinating center. Creatine kinase (CK) and CK-MB levels were assessed at baseline and every 8 hours for a minimum of 2 samples after the procedure and assayed using each site's clinical laboratory and reference values. If myocardial infarction (MI) was suspected clinically at a later point, additional biomarkers were obtained.



Patients were contacted by telephone at 6 and 12 months after the index PCI. Events noted at follow-up included stent thrombosis, death, revascularization, MI, and noncardiac surgery. The use of aspirin and clopidogrel was also assessed at each time point. The study protocol was approved by ethical review committees at all participating institutions; all patients provided written informed consent.

Patient Population

For the present analysis, we included all patients who underwent PCI for reasons other than ST-elevation MI, had baseline CK-MB measured, and received at least 1 drug-eluting stent in the first 2 waves of EVENT. Patients who received a bare-metal and 1 or more drug-eluting stents were analyzed (as specified in the study protocol) as having received a drug-eluting stent and were included in the current analysis while 339 patients (6.7%) receiving bare-metal stents only and 48 (0.9%) in whom no stent could be implanted were not included.

Patients were divided into 2 groups based on the presence of at least 1 of 9 characteristics that would have excluded them from the pivotal clinical trials submitted for the current label approvals of drug-eluting stents. Because the clinical characteristics required for enrollment in the Sirolimus-Coated Bx Velocity Balloon-Expandable Stent in the Treatment of Patients With de novo Coronary Artery Lesions (SIRIUS) and TAXUS IV trials[3,4] differed slightly, an amalgamated definition of off-label characteristics was adopted (TABLE 1). Patients not meeting at least 1 of these criteria were designated as the on-label group.

Definitions, Adjudication of Events, and Study Outcomes

The primary end points were the composite of death, MI, or target vessel revascularization during the index hospitalization and death, MI, or target lesion revascularization at follow-up. The definition of MI was elevation of CK-MB or CK at least 3 times the local upper limit of normal with preference given to the MB values, or persistent ST-segment elevation greater than 1 mm in 2 contiguous electrocardiographic limb leads or greater than 2 mm in 2 contiguous precordial leads. For patients whose CK-MB (or CK) level was elevated at baseline, an increase of at least 2-fold compared with the baseline was also required.

Suspected MIs were adjudicated by 2 independent cardiologists without knowledge of the label status of the patient. Additional end points included death, coronary artery bypass graft surgery, repeat PCI, and major bleeding (defined by the Thrombolysis in MI [TIMI] criteria).[7] Lesion complexity[8] and angiographic success (residual stenosis <20% and TIMI grade 3 flow) were determined by the operator, as were stent thromboses. Repeat revascularization procedures were categorized by investigators as urgent or planned.

Statistical Methods

Continuous variables were compared with the *t* test. Dichotomous or nominal categorical variables were compared with the χ^2 test with normal approximation or Fisher exact test when appropriate, while ordinal variables were compared with Wilcoxon rank sum test. To test the association between label status and in-hospital clinical outcomes, odds ratios and their 95% confidence intervals (CIs) were calculated using logistic regression. For 6-month and 12-month clinical outcomes, hazard ratios (HRs) and their 95% CIs were calculated using Cox proportional hazards regression to test the association between label status and outcomes. Kaplan-Meier estimates were used to present event rate graphs for the in-hospital composite end point of death, MI, or target vessel revascularization and of the 6- and 12-month composite end points of death, MI, or target lesion revascularization. Event time distributions were compared using the log-rank test.

Logistic regression was used to identify predictors of in-hospital composite end point of death, MI, or target vessel revascularization and Cox proportional hazards regression was used to identify predictors of the 12-month composite end point of death, MI, or target lesion revascularization. The variables age, sex, diabetes, congestive heart failure, renal dysfunction (creatinine >2 mg/dL [>176.8 µmol/L]), acute coronary syndrome indication, and weight were considered in multivariable analyses as potential predictors. A list of significant variables ($P<.10$) using backward stepwise regression with stay criterion of .10 was generated. The variable *label*

status was then forced into the regression model, which included the significant variables from the backward stepwise logistic regression model to assess the significance of label use in the presence of other significant predictors. To explore the role of antiplatelet therapy on late events, patients were categorized as receiving or not receiving dual antiplatelet therapy (combined aspirin and clopidogrel) at 6 or 12 months. Dual antiplatelet therapy status was subsequently forced into the model to determine whether it exerted an influence, in addition to label status, on the risk of a clinical event. Interaction terms and their 95% CIs were also determined for dual antiplatelet therapy status and label status for each of the outcomes. In a separate analysis, we used multiple logistic regression to identify which off-label characteristics were independently associated with ischemic complications during the index hospitalization and the 6-month and 12-month follow-up periods.

All statistical analyses were performed using SAS 8.2 (SAS Institute, Cary, NC). Unless specified otherwise, a 2-tailed *P* value of ≤.05 was considered statistically significant.

Abbreviations: CI, confidence interval; OR, odds ratio.
*More than one angiographic complication could occur in a single patient.

RESULTS

Between July 2004 and September 2005, 5053 patients were enrolled in waves 1 and 2 of EVENT. Of the 3323 patients eligible for inclusion in the current analysis (FIGURE 1), 1817 (54.7%) had at least 1 off-label criterion. Among the latter group, 784 (43.1%) had 2, and 238 (13.2%) had 3 or more off-label characteristics. Similar proportions of patients in each wave of the registry were categorized as on-label and off-label. Follow-up was completed in 3323 (100%) patients at the time of discharge from index admission and in 3091 (93.2%) patients at 1 year.

Clinical and Angiographic Characteristics

The most common off-label characteristics were multilesion PCI, stent length of at least 36 mm, and treatment of a bifurcation lesion (Table 1.) Male sex, prior congestive heart failure, prior MI, and previous coronary artery bypass surgery graft surgery were more common in the off-label group. Patients in the off-label group were more likely to have acute coronary syndromes or congestive heart failure and less likely to have a positive stress test as indications for intervention and to receive a sirolimus-eluting stent or an additional bare-metal stent (TABLE 2).

Use of a 300 mg loading dose of clopidogrel 6 or more hours prior to the procedure or upstream glycoprotein IIb/IIIa antagonist use were slightly more common among the off-label group. Direct thrombin inhibitors were used less commonly in the off-label group. Peak activated clotting times were not different between groups (TABLE 3).

Downloaded from www.jama.com at Duke University on April 17, 2009

Angiographic Outcomes and Events During Index Hospitalization

Angiographic success rates exceeded 97% in each group. Acute angiographic complications were more common in the off-label group (TABLE 4). All episodes of stent thrombosis during hospitalization occurred in the off-label group (8 [0.4%]) vs 0 [0%]).

The primary composite outcome occurred more often in the off-label group (TABLE 5). This difference was primarily due to a higher frequency of MI in the off-label group. Both large and small periprocedural infarctions were more common in the off-label group. Major bleeding occurred in 5 (0.3%) of 1817 patients in the off-label group vs 7 (0.5%) of 1506 patients in the on-label group and blood transfusion occurred in 40 (2.2) of 1817 in the off-label group and 22 (1.5%) of 1506 in the on-label group.

Outcomes at 1 Year

At one year, there was no difference in mortality between the groups. The composite outcome occurred more often in the off-label group: 309 (17.5%) vs 131 (8.9%), adjusted HR, 2.16 (95% CI, 1.74-2.67). Stent thrombosis also occurred more frequently in off-label patients: 29 (1.6%) vs 12 (0.9%) multivariable adjusted HR, 2.29 (95% CI, 1.02-5.16; $P<.001$; (FIGURE 2 and TABLE 6). Use of clopidogrel and aspirin was more than 75% in both groups at 12 months. When dual antiplatelet therapy status was forced into the model, there was little change in the excess risk associated with label status for the composite end point (adjusted HR, 2.17; 95% CI, 1.71-2.74; $P<.001$) or for stent thrombosis (adjusted HR, 2.63; 95% CI, 1.12-6.15, $P=.03$). Similarly, when 6-month dual antiplatelet status was forced into the model for 12-month outcomes, the adjusted odds ratios were very similar (for the composite end point HR, 2.24; 95% CI 1.75-2.89, and for stent thrombosis adjusted HR, 2.76; 95% CI, 1.18-6.48). There was no evidence of interaction between label status and concurrent dual antiplatelet therapy status, nor between 6-month dual antiplatelet therapy status for any of the outcomes at 6 or 12 months.

Characteristics Predicting Clinical Outcomes

Off-label drug-eluting stents use was independently associated with an increased risk of ischemic complications during the index hospitalization and at 1 year (TABLE 7). When individual off-label characteristics were subsequently forced into the model, stent length of 36 mm or longer, ejection fraction of less than 25%, and coronary bypass graft surgery lesions remained independent predictors of the composite end point at 1 year (FIGURE 3).

COMMENT

The first 2 waves of EVENT provided a unique opportunity to evaluate the contemporary use of drug-eluting stents as they were introduced into clinical practice. In this study we assessed the use of drug-eluting stents, and associated clinical and procedural outcomes, in common clinical settings not tested in the pivotal randomized trials. In contrast to other administrative and postmarket surveillance registries, periprocedural CK-MB levels, and detailed pharmacological data were collected routinely.

Our first key finding is that among unselected patients undergoing drug-eluting stent placement in contemporary practice, off-label use outnumbered

on-label use. This proportion would have been even higher had patients undergoing primary PCI for ST elevation MI been included in this analysis. Moreover, we found that despite high rates of angiographic success, patients with 1 or more off-label characteristics who received at least 1 drug-eluting stents were more likely to experience an angiographic complication or an adverse cardiovascular event than patients treated for only on-label indications—differences that persisted after adjustment for a broad range of baseline variables. Indeed, off-label status was the strongest independent predictor of both in-hospital and 1-year adverse cardiac events in the multivariate model.

Off-label implantation of drug-eluting stents was also associated with a higher risk of stent thrombosis. All of the episodes of in-hospital stent thrombosis occurred in the off-label group, while in the interval between hospital discharge and 1-year follow-up, the differences in thrombosis rates appeared to narrow.

Comparison With Other Contemporary Data

The American College of Cardiology National Cardiovascular Data Registry (ACC-NCDR) reported that off-label use of drug-eluting stents was associated with a low rate of short-term adverse events compared with results predicted using a previously validated model.[9] Several factors may explain the differences between ACC/NCDR results and our findings. First, the definition of off-label use in the former study was less inclusive than that used in the current analysis. In contrast to ACC-NCDR, EVENT required rigorous assessment for periprocedural MI by evaluation of serial cardiac enzymes. As a result, adverse event rates in EVENT were substantially higher than those detected in most other "real-world" registries that have used less rigorous ascertainment techniques. Several small randomized trials and registries have assessed the utility of drug-eluting stents in a variety of lesion subsets that were not included in the pivotal clinical trials.[10-13] Enrollment in these studies was limited to specific lesion characteristics, while most patients in the off-label group in EVENT had multiple off-label characteristics, resulting in a higher acuity population than was represented in the lesion-specific trials.

Risk of Off-Label Use of Drug-Eluting Stents in Real-Life Settings

The risk associated with off-label use of drug-eluting stents was not limited to the periprocedural period, but continued to accrue after hospital discharge. Indeed, between discharge and 1-year, the composite outcome of death, MI, and target vessel revascularization occurred in 6.6% of patients in the off-label group and 3.9% in the on-label group. Only a small proportion of this difference could be attributed to late stent thrombosis. It has been observed that medication compli-

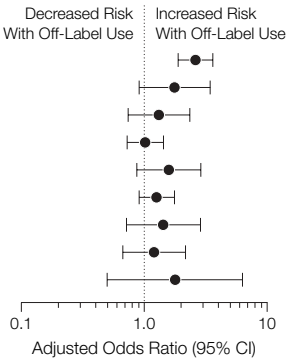
ance is generally overestimated in randomized clinical trials compared with the general population.[14] Data from the Prospective Registry Evaluating Myocardial Infarction: Event Recovery (PREMIER) Registry showed that only 86% of drug-eluting stent–treated MI patients discharged with thienopyridine medication continued taking the therapy after 30 days.[15] It is noteworthy that in the current study, the events detected at follow-up occurred despite more than 75% use of aspirin and clopidogrel and frequent use of β-blockers. In addition, the use or disuse of dual-antiplatelet therapy did not explain the increased risk of experiencing 1 of the composite end points or of stent thrombosis at either 6 or 12 months associated with off-label use of drug-eluting stents in EVENT.



Implications

Although the current report presents only 12-month follow-up from 2 of the

first 4 waves in EVENT, we believe that data from this period are critically important because they represent a cross-section of clinical practice at a crucial point in the development of drug-eluting stents. By the time enrollment in EVENT began, drug-eluting stent use had reached an early stage of maturity. Emerging intermediate-term follow-up of studies comparing bare-metal and drug-eluting stent implantation during this period has included signals of a hazard associated with drug-eluting stents use.[16,17] EVENT is not device specific and enrolls unselected patients. As such, it provides a valuable snapshot of the index stent implantations whose long-term outcomes are beginning to emerge in follow-up studies. The findings indicate a tendency to select relatively long stents, aggressive use of glycoprotein IIb/IIIa antagonists, and high use of aspirin and clopidogrel at 12 months, although the implementation of clopidogrel loading prior to PCI is probably suboptimal. The findings also indicate a relatively high rate of periprocedural MI despite these aggressive measures, and as in a report from the Evaluation of Platelet IIb/IIIa Inhibitor for Stenting (EPISTENT) trial by Cura et al,[18] most events in a stent population occurred in patients with angiographically complex lesions.

Limitations

These results should be interpreted with several caveats. First, by definition, registries do not include control groups. We therefore did not compare patients receiving drug-eluting stents off-label to concurrent patients receiving bare-metal stents for the same indications, nor did we compare them to patients undergoing coronary artery bypass graft surgery, perhaps a more appropriate comparator for some subgroups. Thus, the current observations do not allow differentiation of follow-up events resulting from more severe underlying disease in the off-label patients from those that are consequences of the stent implantation. Registries that have made this comparison have indicated favorable results for stenting[19] and several randomized comparisons are under way.[20,21] Second, although each reported stent thrombosis was adjudicated, the frequency of stent thrombosis was determined based on investigator observation rather than the recently developed Academic Research Consortium (ARC) definitions.[22] Third, the challenge of adjudicating periprocedural events in patients with elevated baseline CK or evolving acute coronary syndromes at the time of PCI has been recognized.[23] To improve specificity, the definition of post-PCI MI required a 3-fold increase in CK-MB levels for such patients.[7] Fourth, although the criteria defining the off-label group do not reflect verbatim the approved stent labels, they duplicate the criteria that excluded patients from inclusion in the trials used to support the currently approved labels for drug-eluting stents available in the United States. Finally, the current report consists of events observed up to one year and does not address the concerns of longer-term follow-up. In particular, several recent observations[24-26] suggest a persistently increased hazard of very late ischemic events when dual antiplatelet therapy is stopped 6 or 12 months after PCI. As a result, informal surveys suggest that the use of drug-eluting stents has declined slightly in recent months.[27] Whether this hazard is assumed primarily by high-risk (ie, off-label) or is also encountered by low risk (on-label) patients will need to be answered in longer-term follow-up.

CONCLUSIONS

Off-label use of drug-eluting stents is more common than on-label use and is associated with a persistently higher rate of adverse angiographic and clinical outcomes. In particular, stent thrombosis was observed predominantly in patients who underwent drug-eluting stents implantation for an off-label indication. Several specific off-label angiographic and clinical characteristics seemed to be associated with the highest incidence of adverse clinical events. Cinicians should be cautious about extrapolating the benefits of drug-eluting stents compared with bare-metal stents that were observed in randomized clinical trials to higher-risk clinical settings that have not been assessed. Whether drug-eluting stents should be used routinely in more complex patient subsets requires further study.

Author Contributions: Dr Kleiman had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.
Study concept and design: Cohen, Kleiman.
Acquisition of data: Maresh, Lopez, Rihal, Parikh, Granada, Nassif.
Analysis and interpretation of data: Win, Caldera, Lopez, Parikh, Granada, Marulkar, Nassif, Cohen, Kleiman.

Preamble

The medical profession should play a central role in evaluating the evidence related to drugs, devices, and procedures for the detection, management, and prevention of disease. When properly applied, expert analysis of available data on the benefits and risks of these therapies and procedures can improve the quality of care, optimize patient outcomes, and favorably affect costs by focusing resources on the most effective strategies. An organized and directed approach to a thorough review of evidence has resulted in the production of clinical practice guidelines that assist physicians in selecting the best management strategy for an individual patient. Moreover, clinical practice guidelines can provide a foundation for other applications, such as performance measures, appropriate use criteria, and both quality improvement and clinical decision support tools.

The American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA) have jointly produced guidelines in the area of cardiovascular disease since 1980. The ACCF/AHA Task Force on Practice Guidelines (Task Force), charged with developing, updating, and revising practice guidelines for cardiovascular diseases and procedures, directs and oversees this effort. Writing committees are charged with regularly reviewing and evaluating all available evidence to develop balanced, patient-centric recommendations for clinical practice.

Experts in the subject under consideration are selected by the ACCF and AHA to examine subject-specific data and write guidelines in partnership with representatives from other medical organizations and specialty groups. Writing committees are asked to perform a formal literature review; weigh the strength of evidence for or against particular tests, treatments, or procedures; and include estimates of expected outcomes where such data exist. Patient-specific modifiers, comorbidities, and issues of patient preference that may influence the choice of tests or therapies are considered. When available, information from studies on cost is considered, but data on efficacy and outcomes constitute the primary basis for the recommendations contained herein.

In analyzing the data and developing recommendations and supporting text, the writing committee uses evidence-based methodologies developed by the Task Force (1). The Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm. The Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect. The writing committee reviews and ranks evidence supporting each recommendation with the weight of evidence ranked as LOE A, B, or C according to specific definitions that are included in Table 1. Studies are identified as observational, retrospective, prospective, or randomized where appropriate. For certain conditions for which inadequate data are available, recommendations are based on expert consensus and clinical experience and are ranked as LOE C. When recommendations at LOE C are supported by historical clinical data, appropriate references (including clinical reviews) are cited if available. For issues for which sparse data are available, a survey of current

Table 1. Applying Classification of Recommendations and Level of Evidence

ESTIMATE OF CERTAINTY (PRECISION) OF TREATMENT EFFECT	CLASS I *Benefit >>> Risk* Procedure/Treatment **SHOULD** be performed/ administered	CLASS IIa *Benefit >> Risk* *Additional studies with focused objectives needed* **IT IS REASONABLE** to perform procedure/administer treatment	CLASS IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; additional registry data would be helpful* Procedure/Treatment **MAY BE CONSIDERED**	CLASS III *No Benefit* or CLASS III *Harm* Procedure/Test / Treatment COR III: No benefit — Not Helpful / No Proven Benefit COR III: Harm — Excess Cost w/o Benefit or Harmful / Harmful to Patients
LEVEL A Multiple populations evaluated* Data derived from multiple randomized clinical trials or meta-analyses	■ Recommendation that procedure or treatment is useful/effective ■ Sufficient evidence from multiple randomized trials or meta-analyses	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from multiple randomized trials or meta-analyses	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Sufficient evidence from multiple randomized trials or meta-analyses
LEVEL B Limited populations evaluated* Data derived from a single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is useful/effective ■ Evidence from single randomized trial or nonrandomized studies	■ Recommendation in favor of treatment or procedure being useful/effective ■ Some conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation's usefulness/efficacy less well established ■ Greater conflicting evidence from single randomized trial or nonrandomized studies	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Evidence from single randomized trial or nonrandomized studies
LEVEL C Very limited populations evaluated* Only consensus opinion of experts, case studies, or standard of care	■ Recommendation that procedure or treatment is useful/effective ■ Only expert opinion, case studies, or standard of care	■ Recommendation in favor of treatment or procedure being useful/effective ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation's usefulness/efficacy less well established ■ Only diverging expert opinion, case studies, or standard of care	■ Recommendation that procedure or treatment is not useful/effective and may be harmful ■ Only expert opinion, case studies, or standard of care
Suggested phrases for writing recommendations	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown/unclear/uncertain or not well established	COR III: No Benefit: is not recommended; is not indicated; should not be performed/ administered/ other; is not useful/ beneficial/ effective COR III: Harm: potentially harmful; causes harm; associated with excess morbidity/mortality; should not be performed/ administered/ other
Comparative effectiveness phrases†	treatment/strategy A is recommended/indicated in preference to treatment B treatment A should be chosen over treatment B	treatment/strategy A is probably recommended/indicated in preference to treatment B it is reasonable to choose treatment A over treatment B		

A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use. †For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

practice among the clinicians on the writing committee is the basis for LOE C recommendations and no references are cited. The schema for COR and LOE is summarized in Table 1, which also provides suggested phrases for writing recommendations within each COR. A new addition to this methodology is separation of the Class III recommendations to delineate if the recommendation is determined to be of "no benefit" or is associated with "harm" to the patient. In addition, in view of the increasing number of comparative effectiveness studies, comparator verbs and suggested phrases for writing recommendations for the comparative effectiveness of one treatment or strategy versus another have been added for COR I and IIa, LOE A or B only.

In view of the advances in medical therapy across the spectrum of cardiovascular diseases, the Task Force has designated the term *guideline-directed medical therapy (GDMT)* to represent optimal medical therapy as defined by ACCF/AHA guideline recommended therapies (primarily Class I). This new term, GDMT, will be used herein and throughout all future guidelines.

Because the ACCF/AHA practice guidelines address patient populations (and healthcare providers) residing in North America, drugs that are not currently available in North America are discussed in the text without a specific COR. For studies performed in large numbers of subjects outside North America, each writing committee reviews the potential influence of different practice patterns and patient

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

populations on the treatment effect and relevance to the ACCF/AHA target population to determine whether the findings should inform a specific recommendation.

The ACCF/AHA practice guidelines are intended to assist healthcare providers in clinical decision making by describing a range of generally acceptable approaches to the diagnosis, management, and prevention of specific diseases or conditions. The guidelines attempt to define practices that meet the needs of most patients in most circumstances. The ultimate judgment regarding care of a particular patient must be made by the healthcare provider and patient in light of all the circumstances presented by that patient. As a result, situations may arise for which deviations from these guidelines may be appropriate. Clinical decision making should involve consideration of the quality and availability of expertise in the area where care is provided. When these guidelines are used as the basis for regulatory or payer decisions, the goal should be improvement in quality of care. The Task Force recognizes that situations arise in which additional data are needed to inform patient care more effectively; these areas will be identified within each respective guideline when appropriate.

Prescribed courses of treatment in accordance with these recommendations are effective only if followed. Because lack of patient understanding and adherence may adversely affect outcomes, physicians and other healthcare providers should make every effort to engage the patient's active participation in prescribed medical regimens and lifestyles. In addition, patients should be informed of the risks, benefits, and alternatives to a particular treatment and be involved in shared decision making whenever feasible, particularly for COR IIa and IIb, where the benefit-to-risk ratio may be lower.

The Task Force makes every effort to avoid actual, potential, or perceived conflicts of interest that may arise as a result of industry relationships or personal interests among the members of the writing committee. All writing committee members and peer reviewers of the guideline are asked to disclose all such current relationships, as well as those existing 12 months previously. In December 2009, the ACCF and AHA implemented a new policy for relationships with industry and other entities (RWI) that requires the writing committee chair plus a minimum of 50% of the writing committee to have no *relevant* RWI (Appendix 1 for the ACCF/AHA definition of relevance). These statements are reviewed by the Task Force and all members during each conference call and/or meeting of the writing committee and are updated as changes occur. All guideline recommendations require a confidential vote by the writing committee and must be approved by a consensus of the voting members. Members are not permitted to write, and must recuse themselves from voting on, any recommendation or section to which their RWI apply. Members who recused themselves from voting are indicated in the list of writing committee members, and section recusals are noted in Appendix 1. Authors' and peer reviewers' RWI pertinent to this guideline are disclosed in Appendixes 1 and 2, respectively. Additionally, to ensure complete transparency, writing committee members' comprehensive disclosure information—including RWI not pertinent to this document—is available as an online supplement. Comprehensive disclosure information for the Task Force is also available online at www.cardiosource.org/ACC/About-ACC/Leadership/Guidelines-and-Documents-Task-Forces.aspx. The work of the writing committee was supported exclusively by the ACCF, AHA, and the Society for Cardiovascular Angiography and Interventions (SCAI) without commercial support. Writing committee members volunteered their time for this activity.

In an effort to maintain relevance at the point of care for practicing physicians, the Task Force continues to oversee an ongoing process improvement initiative. As a result, in response to pilot projects, several changes to these guidelines will be apparent, including limited narrative text, a focus on summary and evidence tables (with references linked to abstracts in PubMed) and more liberal use of summary recommendation tables (with references that support LOE) to serve as a quick reference.

In April 2011, the Institute of Medicine released 2 reports: *Finding What Works in Health Care: Standards for Systematic Reviews* and *Clinical Practice Guidelines We Can Trust* (2,3). It is noteworthy that the ACCF/AHA guidelines were cited as being compliant with many of the standards that were proposed. A thorough review of these reports and of our current methodology is under way, with further enhancements anticipated.

The recommendations in this guideline are considered current until they are superseded by a focused update or the full-text guideline is revised. Guidelines are official policy of both the ACCF and AHA.

Alice K. Jacobs, MD, FACC, FAHA, Chair
ACCF/AHA Task Force on Practice Guidelines

1. Introduction

1.1. Methodology and Evidence Review

The recommendations listed in this document are, whenever possible, evidence based. An extensive evidence review was conducted through November 2010, as well as selected other references through August 2011. Searches were limited to studies, reviews, and other evidence conducted in human subjects and that were published in English. Key search words included but were not limited to the following: *ad hoc angioplasty*, *angioplasty*, *balloon angioplasty*, *clinical trial*, *coronary stenting*, *delayed angioplasty*, *meta-analysis*, *percutaneous transluminal coronary angioplasty*, *randomized controlled trial (RCT)*, *percutaneous coronary intervention (PCI) and angina*, *angina reduction*, *antiplatelet therapy*, *bare-metal stents (BMS)*, *cardiac rehabilitation*, *chronic stable angina*, *complication*, *coronary bifurcation lesion*, *coronary calcified lesion*, *coronary chronic total occlusion (CTO)*, *coronary ostial lesions*, *coronary stent (BMS and drug-eluting stents*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

[DES]; and BMS versus DES, *diabetes*, *distal embolization*, *distal protection*, *elderly*, *ethics*, *late stent thrombosis*, *medical therapy*, *microembolization*, *mortality*, *multiple lesions*, *multivessel*, *myocardial infarction (MI)*, *non–ST-elevation myocardial infarction (NSTEMI)*, *no-reflow*, *optical coherence tomography*, *proton pump inhibitor (PPI)*, *return to work*, *same-day angioplasty and/or stenting*, *slow flow*, *stable ischemic heart disease (SIHD)*, *staged angioplasty*, *STEMI*, *survival*, and *unstable angina (UA)*. Additional searches cross-referenced these topics with the following subtopics: *anticoagulant therapy*, *contrast nephropathy*, *PCI-related vascular complications*, *unprotected left main PCI*, *multivessel coronary artery disease (CAD)*, *adjunctive percutaneous interventional devices*, *percutaneous hemodynamic support devices*, and *secondary prevention*. Additionally, the committee reviewed documents related to the subject matter previously published by the ACCF and AHA. References selected and published in this document are representative and not all-inclusive.

To provide clinicians with a comprehensive set of data, whenever deemed appropriate or when published, the absolute risk difference and number needed to treat or harm will be provided in the guideline, along with confidence intervals (CIs) and data related to the relative treatment effects such as odds ratio (OR), relative risk, hazard ratio (HR), or incidence rate ratio.

The focus of this guideline is the safe, appropriate, and efficacious performance of PCI. The risks of PCI must be balanced against the likelihood of improved survival, symptoms, or functional status. This is especially important in patients with SIHD.

1.2. Organization of the Writing Committee

The committee was composed of physicians with expertise in interventional cardiology, general cardiology, critical care cardiology, cardiothoracic surgery, clinical trials, and health services research. The committee included representatives from the ACCF, AHA, and SCAI.

1.3. Document Review and Approval

This document was reviewed by 2 official reviewers nominated by the ACCF, AHA, and SCAI, as well as 21 individual content reviewers (including members of the ACCF Interventional Scientific Council and ACCF Surgeons' Scientific Council). All information on reviewers' RWI was distributed to the writing committee and is published in this document (Appendix 2). This document was approved for publication by the governing bodies of the ACCF, AHA, and SCAI.

1.4. PCI Guidelines: History and Evolution

In 1982, a 2-page manuscript titled "Guidelines for the Performance of Percutaneous Transluminal Coronary Angioplasty" was published in *Circulation* (4). The document, which addressed the specific expertise and experience physicians should have to perform balloon angioplasty, as well as laboratory requirements and the need for surgical support, was written by an ad hoc group whose members included Andreas Grüntzig. In 1980, the ACC and the AHA established the Task Force on Assessment of Diagnostic and Therapeutic Cardiovascular Procedures, which was charged with the development of guidelines related to the role of new therapeutic approaches and of specific noninvasive and invasive procedures in the diagnosis and management of cardiovascular disease. The first ACC/AHA Task Force report on guidelines for coronary balloon angioplasty was published in 1988 (5). The 18-page document discussed and made recommendations about lesion classification and success rates, indications for and contraindications to balloon angioplasty, institutional review of angioplasty procedures, ad hoc angioplasty after angiography, and on-site surgical backup. Further iterations of the guidelines were published in 1993 (6), 2001 (7), and 2005 (8). In 2007 and 2009, focused updates to the guideline were published to expeditiously address new study results and recent changes in the field of interventional cardiology (9,10). The 2009 focused update is notable in that there was direct collaboration between the writing committees for the STEMI guidelines and the PCI guidelines, resulting in a single publication of focused updates on STEMI and PCI (10).

The evolution of the PCI guideline reflects the growth of knowledge in the field and parallels the many advances and innovations in the field of interventional cardiology, including primary PCI, BMS and DES, intravascular ultrasound (IVUS) and physiologic assessments of stenosis, and newer antiplatelet and anticoagulant therapies. The 2011 iteration of the guideline continues this process, addressing ethical aspects of PCI, vascular access considerations, CAD revascularization including hybrid revascularization, revascularization before noncardiac surgery, optical coherence tomography, advanced hemodynamic support devices, no-reflow therapies, and vascular closure devices. Most of this document is organized according to "patient flow," consisting of preprocedural considerations, procedural considerations, and postprocedural considerations. In a major undertaking, the STEMI, PCI, and coronary artery bypass graft (CABG) surgery guidelines were written concurrently, with additional collaboration with the SIHD guideline writing committee, allowing greater collaboration between the different writing committees on topics such as PCI in STEMI and revascularization strategies in patients with CAD (including unprotected left main PCI, multivessel disease revascularization, and hybrid procedures).

In accordance with direction from the Task Force and feedback from readers, in this iteration of the guideline, the text has been shortened, with an emphasis on summary statements rather than detailed discussion of numerous individual trials. Online supplemental evidence and summary tables have been created to document the

ARTICLE IN PRESS

studies and data considered for new or changed guideline recommendations.

2. CAD Revascularization

Recommendations and text in this section are the result of extensive collaborative discussions between the PCI and CABG writing committees, as well as key members of the SIHD and UA/NSTEMI writing committees. Certain issues, such as older versus more contemporary studies, primary analyses versus subgroup analyses, and prospective versus post hoc analyses, have been carefully weighed in designating COR and LOE; they are addressed in the appropriate corresponding text. The goals of revascularization for patients with CAD are to 1) improve survival and/or 2) relieve symptoms.

Revascularization recommendations in this section are predominantly based on studies of patients with symptomatic SIHD and should be interpreted in this context. As discussed later in this section, recommendations on the type of revascularization are, in general, applicable to patients with UA/NSTEMI. In some cases (e.g., unprotected left main CAD), specific recommendations are made for patients with UA/NSTEMI or STEMI.

Historically, most studies of revascularization have been based on and reported according to angiographic criteria. Most studies have defined a "significant" stenosis as ≥70% diameter narrowing; therefore, for revascularization decisions and recommendations in this section, a "significant" stenosis has been defined as ≥70% diameter narrowing (≥50% for left main CAD). Physiological criteria, such as an assessment of fractional flow reserve (FFR), has been used in deciding when revascularization is indicated. Thus, for recommendations about revascularization in this section, coronary stenoses with FFR ≤0.80 can also be considered to be "significant" (11,12).

As noted, the revascularization recommendations have been formulated to address issues related to 1) improved survival and/or 2) improved symptoms. When one method of revascularization is preferred over the other for improved survival, this consideration, in general, takes precedence over improved symptoms. When discussing options for revascularization with the patient, he or she should understand when the procedure is being performed in an attempt to improve symptoms, survival, or both.

Although some results from the SYNTAX (Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery) study are best characterized as subgroup analyses and "hypothesis generating," SYNTAX nonetheless represents the latest and most comprehensive comparison of PCI and CABG (13,14). Therefore, the results of SYNTAX have been considered appropriately when formulating our revascularization recommendations. Although the limitations of using the SYNTAX score for certain revascularization recommendations are recognized, the SYNTAX score is a reasonable surrogate for the extent of CAD and its complexity and serves as important information that should be considered when making revascularization decisions. Recommendations that refer to SYNTAX scores use them as surrogates for the extent and complexity of CAD.

Revascularization recommendations to improve survival and symptoms are provided in the following text and are summarized in Tables 2 and 3. References to studies comparing revascularization with medical therapy are presented when available for each anatomic subgroup.

See Online Data Supplements 1 and 2 for additional data regarding the survival and symptomatic benefits with CABG or PCI for different anatomic subsets.

2.1. Heart Team Approach to Revascularization Decisions: Recommendations

CLASS I

1. A Heart Team approach to revascularization is recommended in patients with unprotected left main or complex CAD (14–16). *(Level of Evidence: C)*

CLASS IIa

1. Calculation of the Society of Thoracic Surgeons (STS) and SYNTAX scores is reasonable in patients with unprotected left main and complex CAD (13,14,17–22). *(Level of Evidence: B)*

One protocol used in RCTs (14–16,23) often involves a multidisciplinary approach referred to as the Heart Team. Composed of an interventional cardiologist and a cardiac surgeon, the Heart Team 1) reviews the patient's medical condition and coronary anatomy, 2) determines that PCI and/or CABG are technically feasible and reasonable, and 3) discusses revascularization options with the patient before a treatment strategy is selected. Support for using a Heart Team approach comes from reports that patients with complex CAD referred specifically for PCI or CABG in concurrent trial registries have lower mortality rates than those randomly assigned to PCI or CABG in controlled trials (15,16).

The SIHD, PCI, and CABG guideline writing committees endorse a Heart Team approach in patients with unprotected left main CAD and/or complex CAD in whom the optimal revascularization strategy is not straightforward. A collaborative assessment of revascularization options, or the decision to treat with GDMT without revascularization, involving an interventional cardiologist, a cardiac surgeon, and (often) the patient's general cardiologist, followed by discussion with the patient about treatment options, is optimal. Particularly in patients with SIHD and unprotected left main and/or complex CAD for whom a revascularization strategy is not straightforward, an approach has been endorsed that involves terminating the procedure after diagnostic coronary angiography is completed: this allows a thorough discussion and affords both the interventional

Complex 3-vessel CAD (e.g., SYNTAX score >22) with or without involvement of the proximal LAD artery and a good candidate for CABG	IIa—CABG preferred over PCI	B	(32,46,56,71,72)
Viable ischemic myocardium that is perfused by coronary arteries that are not amenable to grafting	IIb—TMR as an adjunct to CABG	B	(109–113)
No anatomic or physiologic criteria for revascularization	III: Harm—CABG III: Harm—PCI	C	N/A

CABG indicates coronary artery bypass graft; CAD, coronary artery disease; COR, class of recommendation; FFR, fractional flow reserve; GDMT, guideline-directed medical therapy; LOE, level of evidence; N/A, not applicable; PCI, percutaneous coronary intervention; SYNTAX, Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery; and TMR, transmyocardial laser revascularization.

cardiologist and cardiac surgeon the opportunity to discuss revascularization options with the patient. Because the STS score and the SYNTAX score have been shown to predict adverse outcomes in patients undergoing CABG and PCI, respectively, calculation of these scores is often useful in making revascularization decisions (13,14,17–22).

2.2. Revascularization to Improve Survival: Recommendations

Left Main CAD Revascularization

CLASS I

1. CABG to improve survival is recommended for patients with significant (≥50% diameter stenosis) left main coronary artery stenosis (24–30). *(Level of Evidence: B)*

CLASS IIa

1. PCI to improve survival is reasonable as an alternative to CABG in selected stable patients with significant (≥50% diameter stenosis) unprotected left main CAD with: 1) anatomic conditions associated with a low risk of PCI procedural complications and a high likelihood of good long-term outcome (e.g., a low SYNTAX score [≤22], ostial or trunk left main CAD); and 2) clinical characteristics that predict a significantly increased risk of adverse surgical outcomes (e.g., STS-predicted risk of operative mortality ≥5%) (13,17,19,23,31–48). *(Level of Evidence: B)*
2. PCI to improve survival is reasonable in patients with UA/NSTEMI when an unprotected left main coronary artery is the culprit lesion and the patient is not a candidate for CABG (13,36–39,44,45,47–49). *(Level of Evidence: B)*
3. PCI to improve survival is reasonable in patients with acute STEMI when an unprotected left main coronary artery is the culprit lesion, distal coronary flow is less than TIMI (Thrombolysis In Myocardial Infarction) grade 3, and PCI can be performed more rapidly and safely than CABG (33,50,51). *(Level of Evidence: C)*

CLASS IIb

1. PCI to improve survival may be reasonable as an alternative to CABG in selected stable patients with significant (≥50% diameter stenosis) unprotected left main CAD with: 1) anatomic conditions associated with a low to intermediate risk of PCI procedural complications and an intermediate to high likelihood of good long-term outcome (e.g., low-intermediate SYNTAX score of <33, bifurcation left main CAD); and 2) clinical characteristics that predict an increased risk of adverse surgical outcomes (e.g., moderate-severe chronic obstructive pulmonary disease, disability from previous stroke, or previous cardiac surgery; STS-predicted risk of operative mortality >2%) (13,17,19,23,31–48,52). *(Level of Evidence: B)*

CLASS III: HARM

1. PCI to improve survival should not be performed in stable patients with significant (≥50% diameter stenosis) unprotected left main CAD who have unfavorable anatomy for PCI and who are good candidates for CABG (13,17,19,24–32). *(Level of Evidence: B)*

Non–Left Main CAD Revascularization

CLASS I

1. CABG to improve survival is beneficial in patients with significant (≥70% diameter) stenoses in 3 major coronary arteries (with or without involvement of the proximal left anterior descending [LAD] artery) or in the proximal LAD plus 1 other major coronary artery (26,30,53–56). *(Level of Evidence: B)*
2. CABG or PCI to improve survival is beneficial in survivors of sudden cardiac death with presumed ischemia-mediated ventricular tachycardia caused by significant (≥70% diameter) stenosis in a major coronary artery. *(CABG Level of Evidence: B* [57–59]*; PCI Level of Evidence: C* [57]*)*

CLASS IIa

1. CABG to improve survival is reasonable in patients with significant (≥70% diameter) stenoses in 2 major coronary arteries with severe or extensive myocardial ischemia (e.g., high-risk criteria on stress testing, abnormal intracoronary hemodynamic evaluation, or >20% perfusion defect by myocardial perfusion stress imaging) or target vessels supplying a large area of viable myocardium (60–63). *(Level of Evidence: B)*
2. CABG to improve survival is reasonable in patients with mild-moderate left ventricular (LV) systolic dysfunction (ejection fraction [EF] 35% to 50%) and significant (≥70% diameter stenosis) multivessel CAD or proximal LAD coronary artery stenosis, when viable myocardium is present in the region of intended revascularization (30,64–68). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

3. CABG with a left internal mammary artery (LIMA) graft to improve survival is reasonable in patients with significant (≥70% diameter) stenosis in the proximal LAD artery and evidence of extensive ischemia (30,56,69,70). *(Level of Evidence: B)*
4. It is reasonable to choose CABG over PCI to improve survival in patients with complex 3-vessel CAD (e.g., SYNTAX score >22), with or without involvement of the proximal LAD artery who are good candidates for CABG (32,46,56,71,72). *(Level of Evidence: B)*
5. CABG is probably recommended in preference to PCI to improve survival in patients with multivessel CAD and diabetes mellitus, particularly if a LIMA graft can be anastomosed to the LAD artery (62,74–81). *(Level of Evidence: B)*

CLASS IIb

1. The usefulness of CABG to improve survival is uncertain in patients with significant (≥70%) diameter stenoses in 2 major coronary arteries not involving the proximal LAD artery and without extensive ischemia (56). *(Level of Evidence: C)*
2. The usefulness of PCI to improve survival is uncertain in patients with 2- or 3-vessel CAD (with or without involvement of the proximal LAD artery) or 1-vessel proximal LAD disease (26,53,56,82). *(Level of Evidence: B)*
3. CABG might be considered with the primary or sole intent of improving survival in patients with SIHD with severe LV systolic dysfunction (EF <35%) whether or not viable myocardium is present (30,64–68,83,84). *(Level of Evidence: B)*
4. The usefulness of CABG or PCI to improve survival is uncertain in patients with previous CABG and extensive anterior wall ischemia on noninvasive testing (85–93). *(Level of Evidence: B)*

CLASS III: HARM

1. CABG or PCI should not be performed with the primary or sole intent to improve survival in patients with SIHD with 1 or more coronary stenoses that are not anatomically or functionally significant (e.g., <70% diameter non–left main coronary artery stenosis, FFR >0.80, no or only mild ischemia on noninvasive testing), involve only the left circumflex or right coronary artery, or subtend only a small area of viable myocardium (30,53,60,61,94–98). *(Level of Evidence: B)*

2.3. Revascularization to Improve Symptoms: Recommendations

CLASS I

1. CABG or PCI to improve symptoms is beneficial in patients with 1 or more significant (≥70% diameter) coronary artery stenoses amenable to revascularization and unacceptable angina despite GDMT (82,99–108). *(Level of Evidence: A)*

CLASS IIa

1. CABG or PCI to improve symptoms is reasonable in patients with 1 or more significant (≥70% diameter) coronary artery stenoses and unacceptable angina for whom GDMT cannot be implemented because of medication contraindications, adverse effects, or patient preferences. *(Level of Evidence: C)*
2. PCI to improve symptoms is reasonable in patients with previous CABG, 1 or more significant (≥70% diameter) coronary artery stenoses associated with ischemia, and unacceptable angina despite GDMT (86,89,92). *(Level of Evidence: C)*
3. It is reasonable to choose CABG over PCI to improve symptoms in patients with complex 3-vessel CAD (e.g., SYNTAX score >22), with or without involvement of the proximal LAD artery who are good candidates for CABG (32,46,56,72,73). *(Level of Evidence: B)*

CLASS IIb

1. CABG to improve symptoms might be reasonable for patients with previous CABG, 1 or more significant (≥70% diameter) coronary artery stenoses not amenable to PCI, and unacceptable angina despite GDMT (93). *(Level of Evidence: C)*
2. Transmyocardial laser revascularization (TMR) performed as an adjunct to CABG to improve symptoms may be reasonable in patients with viable ischemic myocardium that is perfused by arteries that are not amenable to grafting (109–113). *(Level of Evidence: B)*

CLASS III: HARM

1. CABG or PCI to improve symptoms should not be performed in patients who do not meet anatomic (≥50% diameter left main or ≥70% non–left main stenosis diameter) or physiological (e.g., abnormal FFR) criteria for revascularization. *(Level of Evidence: C)*

2.4. CABG Versus Contemporaneous Medical Therapy

In the 1970s and 1980s, 3 RCTs established the survival benefit of CABG compared with contemporaneous (although minimal by current standards) medical therapy without revascularization in certain subjects with stable angina: the Veterans Affairs Cooperative Study (114), European Coronary Surgery Study (55), and CASS (Coronary Artery Surgery Study) (115). Subsequently, a 1994 meta-analysis of 7 studies that randomized a total of 2,649 patients to medical therapy or CABG (30) showed that CABG offered a survival advantage over medical therapy for patients with left main or 3-vessel CAD. The studies also established that CABG is more effective than medical therapy for relieving anginal symptoms. These studies have been replicated only once during the past decade. In MASS II (Medicine, Angioplasty, or Surgery Study II), patients with multivessel CAD who were treated with CABG were less likely than those treated with medical therapy to have a subsequent MI, need additional revascularization, or experience cardiac death in the 10 years after randomization (104).

Surgical techniques and medical therapy have improved substantially during the intervening years. As a result, if CABG were to be compared with GDMT in RCTs today, the relative benefits for survival and angina relief observed several decades ago might no longer be observed. Conversely, the concurrent administration of GDMT may substantially improve long-term outcomes in patients treated with CABG in comparison with those receiving medical therapy alone. In the BARI 2D (Bypass Angioplasty Revascularization Investigation 2 Diabetes) trial of patients with diabetes mellitus, no significant difference in risk of mortality in the cohort of patients randomized to GDMT plus CABG or GDMT alone was observed, although the study was not powered for this endpoint, excluded patients with significant left main CAD, and included only a small percentage of patients with proximal

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

LAD artery disease or LV ejection fraction (LVEF) <0.50 (116). The PCI and CABG guideline writing committees endorse the performance of the ISCHEMIA (International Study of Comparative Health Effectiveness with Medical and Invasive Approaches) trial, which will provide contemporary data on the optimal management strategy (medical therapy or revascularization with CABG or PCI) of patients with SIHD, including multivessel CAD, and moderate to severe ischemia.

2.5. PCI Versus Medical Therapy

Although contemporary interventional treatments have lowered the risk of restenosis compared with earlier techniques, meta-analyses have failed to show that the introduction of BMS confers a survival advantage over balloon angioplasty (117–119) or that the use of DES confers a survival advantage over BMS (119,120).

No study to date has demonstrated that PCI in patients with SIHD improves survival rates (26,53,56,82,116,119,121–124). Neither COURAGE (Clinical Outcomes Utilizing Revascularization and Aggressive Drug Evaluation) (82) nor BARI 2D (116), which treated all patients with contemporary optimal medical therapy, demonstrated any survival advantage with PCI, although these trials were not specifically powered for this endpoint. Although 1 large analysis evaluating 17 RCTs of PCI versus medical therapy (including 5 trials of subjects with acute coronary syndromes [ACS]) found a 20% reduction in death with PCI compared with medical therapy (123), 2 other large analyses did not (119,122). An evaluation of 13 studies reporting the data from 5,442 patients with nonacute CAD showed no advantage of PCI over medical therapy for the individual endpoints of all-cause death, cardiac death or MI, or nonfatal MI (124). Evaluation of 61 trials of PCI conducted over several decades shows that despite improvements in PCI technology and pharmacotherapy, PCI has not been demonstrated to reduce the risk of death or MI in patients without recent ACS (119).

The findings from individual studies and systematic reviews of PCI versus medical therapy can be summarized as follows:

- PCI reduces the incidence of angina (82,99,104,107,108,125).
- PCI has not been demonstrated to improve survival in stable patients (119,121,122).
- PCI may increase the short-term risk of MI (82,121,125,126).
- PCI does not lower the long-term risk of MI (82,116,119,121,122,126).

2.6. CABG Versus PCI

The results of 26 RCTs comparing CABG and PCI have been published: Of these, 9 compared CABG with balloon angioplasty (75,105,128–142), 14 compared CABG with BMS implantation (88,143–160), and 3 compared CABG with DES implantation (14,161,162).

2.6.1. CABG Versus Balloon Angioplasty or BMS

A systematic review of the 22 RCTs comparing CABG with balloon angioplasty or BMS implantation concluded the following (163):

1. Survival was similar for CABG and PCI (with balloon angioplasty or BMS) at 1 year and 5 years. Survival was similar for CABG and PCI in subjects with 1-vessel CAD (including those with disease of the proximal portion of the LAD artery) or multivessel CAD.
2. Incidence of MI was similar at 5 years after randomization.
3. Procedural stroke occurred more commonly with CABG than with PCI (1.2% versus 0.6%).
4. Relief of angina was accomplished more effectively with CABG than with PCI 1 year after randomization and 5 years after randomization.
5. During the first year after randomization, repeat coronary revascularization was performed less often after CABG than after PCI (3.8% versus 26.5%). This was also demonstrated after 5 years of follow-up (9.8% versus 46.1%). This difference was more pronounced with balloon angioplasty than with BMS.

A collaborative analysis of data from 10 RCTs comparing CABG with balloon angioplasty (6 trials) or with BMS implantation (4 trials) (164) permitted subgroup analyses of the data from the 7,812 patients. No difference was noted with regard to mortality rate 5.9 years after randomization or the composite endpoint of death or MI. Repeat revascularization and angina were noted more frequently in those treated with balloon angioplasty or BMS implantation (164). The major new observation of this analysis was that CABG was associated with better outcomes in patients with diabetes mellitus and in those >65 years old. Of interest, the relative outcomes of CABG and PCI were not influenced by other patient characteristics, including the number of diseased coronary arteries.

The aforementioned meta-analysis and systematic review (163,164) comparing CABG and balloon angioplasty or BMS implantation were limited in several ways:

1. Many trials did not report outcomes for other important patient subsets. For example, the available data are insufficient to determine if race, obesity, renal dysfunction, peripheral arterial disease, or previous coronary revascularization affected the comparative outcomes of CABG and PCI.
2. Most of the patients enrolled in these trials were male, and most had 1- or 2-vessel CAD and normal LV systolic function (EF >50%)—subjects known to be unlikely to derive a survival benefit and less likely to experience complications after CABG (30).
3. The patients enrolled in these trials represented only a small fraction (generally <5% to 10%) of those who were screened. For example, most screened patients with

CABG indicates coronary artery bypass graft; CAD, coronary artery disease; MACE, major adverse cardiovascular event; PCI, percutaneous coronary intervention; and SYNTAX, Synergy between Percutaneous Coronary Intervention with TAXUS and Cardiac Surgery. Adapted with permission from Kappetein (46).

1-vessel CAD and many with 3-vessel CAD were not considered for randomization.

See Online Data Supplements 3 and 4 for additional data comparing CABG with PCI.

2.6.2. CABG Versus DES

Although the results of 9 observational studies comparing CABG and DES implantation have been published (32,165–172), most of them had short (12 to 24 months) follow-up periods. In a meta-analysis of 24,268 patients with multivessel CAD treated with CABG or DES (173), the incidences of death and MI were similar for the 2 procedures, but the frequency with which repeat revascularization was performed was roughly 4 times higher after DES implantation. Only 1 large RCT comparing CABG and DES implantation has been published. The SYNTAX trial randomly assigned 1,800 patients (of a total of 4,337 who were screened) to receive DES or CABG (14,46). Major adverse cardiac events (MACE), a composite of death, stroke, MI, or repeat revascularization during the 3 years after randomization, occurred in 20.2% of CABG patients and 28.0% of those undergoing DES implantation ($p<0.001$). The rates of death and stroke were similar; however, MI (3.6% for CABG, 7.1% for DES) and repeat revascularization (10.7% for CABG, 19.7% for DES) were more likely to occur with DES implantation (46).

In SYNTAX, the extent of CAD was assessed using the SYNTAX score, which is based on the location, severity, and extent of coronary stenoses, with a low score indicating less complicated anatomic CAD. In post hoc analyses, a low score was defined as ≤22; intermediate, 23 to 32; and high, ≥33. The occurrence of MACE correlated with the SYNTAX score for DES patients but not for those undergoing CABG. At 12-month follow-up, the primary endpoint was similar for CABG and DES in those with a low SYNTAX score. In contrast, MACE occurred more often after DES implantation than after CABG in those with an intermediate or high SYNTAX score (14). At 3 years of follow-up, the mortality rate was greater in subjects with 3-vessel CAD treated with PCI than in those treated with CABG (6.2% versus 2.9%). The differences in MACE between those treated with PCI or CABG increased with an increasing SYNTAX score (Figure 1) (46).

Although the utility of using a SYNTAX score in everyday clinical practice remains uncertain, it seems reasonable to conclude from SYNTAX and other data that outcomes of patients undergoing PCI or CABG in those with relatively uncomplicated and lesser degrees of CAD are comparable, whereas in those with complex and diffuse CAD, CABG appears to be preferable (46).

See Online Data Supplements 5 and 6 for additional data comparing CABG with DES.

2.7. Left Main CAD

2.7.1. CABG or PCI Versus Medical Therapy for Left Main CAD

CABG confers a survival benefit over medical therapy in patients with left main CAD. Subgroup analyses from RCTs performed 3 decades ago included 91 patients with left main CAD in the Veterans Administration Cooperative Study (28). A meta-analysis of these trials demonstrated a 66% reduction in relative risk in mortality with CABG, with the benefit extending to 10 years (30). The CASS Registry (24) contained data from 1,484 patients with ≥50% diameter stenosis left main CAD initially treated surgically or nonsurgically. Median survival duration was 13.3 years in the surgical group; and 6.6 years in the medical group. The survival benefit of CABG over medical therapy appeared to extend to 53 asymptomatic patients with left main CAD in the CASS Registry (29). Other therapies that subsequently have been shown to be associated with improved long-term outcome, such as the use of aspirin, statins, and internal mammary artery grafting, were not widely used in that era.

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

RCTs and subgroup analyses that compare PCI with medical therapy in patients with "unprotected" left main CAD do not exist.

2.7.2. Studies Comparing PCI Versus CABG for Left Main CAD

Of all subjects undergoing coronary angiography, approximately 4% are found to have left main CAD (175), >80% of whom have significant (≥70% diameter) stenoses in other epicardial coronary arteries.

Published cohort studies have found that major clinical outcomes are similar with PCI or CABG 1 year after revascularization and that mortality rates are similar at 1, 2, and 5 years of follow-up; however, the risk of needing target-vessel revascularization is significantly higher with stenting than with CABG.

In the SYNTAX trial, 45% of screened patients with unprotected left main CAD had complex disease that prevented randomization; 89% of these underwent CABG (13,14). In addition, 705 of the 1,800 patients who were randomized had revascularization for unprotected left main CAD. The majority of patients with left main CAD and a low SYNTAX score had isolated left main CAD or left main CAD plus 1-vessel CAD; the majority of those with an intermediate score had left main CAD plus 2-vessel CAD; and most of those with a high SYNTAX score had left main CAD plus 3-vessel CAD. At 1 year, rates of all-cause death and MACE were similar for the 2 groups (13). Repeat revascularization rates were higher in the PCI group than the CABG group (11.8% versus 6.5%), but stroke occurred more often in the CABG group (2.7% versus 0.3%). At 3 years of follow-up, the incidence of death in those undergoing left main CAD revascularization with low or intermediate SYNTAX scores (≤32) was 3.7% after PCI and 9.1% after CABG (p=0.03), whereas in those with a high SYNTAX score (≥33), the incidence of death after 3 years was 13.4% after PCI and 7.6% after CABG (p=0.10) (46). Because the primary endpoint of SYNTAX was not met (i.e., noninferiority comparison of CABG and PCI), these subgroup analyses need to be considered in that context.

In the LE MANS (Study of Unprotected Left Main Stenting Versus Bypass Surgery) trial (23), 105 patients with left main CAD were randomized to receive PCI or CABG. Although a low proportion of patients treated with PCI received DES (35%) and a low proportion of patients treated with CABG received internal mammary grafts (72%), the outcomes at 30 days and 1 year were similar between the groups. In the PRECOMBAT (Premier of Randomized Comparison of Bypass Surgery versus Angioplasty Using Sirolimus-Eluting Stent in Patients with Left Main Coronary Artery Disease) trial of 600 patients with left main disease, the composite endpoint of death, MI, or stroke at 2 years occurred in 4.4% of patients treated with PCI patients and 4.7% of patients treated with CABG, but ischemia-driven target-vessel revascularization was more often required in the patients treated with PCI (9.0% versus 4.2%) (52).

The results from these 3 RCTs suggest (but do not definitively prove) that major clinical outcomes in *selected* patients with left main CAD are similar with CABG and PCI at 1- to 2-year follow-up, but repeat revascularization rates are higher after PCI than after CABG. RCTs with extended follow-up of ≥5 years are required to provide definitive conclusions about the optimal treatment of left main CAD. In a meta-analysis of 8 cohort studies and 2 RCTs (41), death, MI, and stroke occurred with similar frequency in the PCI- and CABG-treated patients at 1, 2, and 3 years of follow-up. Target-vessel revascularization was performed more often in the PCI group at 1 year (OR: 4.36), 2 years (OR: 4.20), and 3 years (OR: 3.30).

See Online Data Supplements 7 to 12 for additional data comparing PCI with CABG for left main CAD.

2.7.3. Revascularization Considerations for Left Main CAD

Although CABG has been considered the "gold standard" for unprotected left main CAD revascularization, more recently PCI has emerged as a possible alternative mode of revascularization in carefully selected patients. Lesion location is an important determinant when considering PCI for unprotected left main CAD. Stenting of the left main ostium or trunk is more straightforward than treating distal bifurcation or trifurcation stenoses, which generally requires a greater degree of operator experience and expertise (176). In addition, PCI of bifurcation disease is associated with higher restenosis rates than when disease is confined to the ostium or trunk (39,177). Although lesion location influences technical success and long-term outcomes after PCI, location exerts a negligible influence on the success of CABG. In subgroup analyses, patients with left main CAD and a SYNTAX score ≥33 with more complex or extensive CAD had a higher mortality rate with PCI than with CABG (46). Physicians can estimate operative risk for all CABG candidates using a standard instrument, such as the risk calculator from the STS database. The above considerations are important factors when choosing among revascularization strategies for unprotected left main CAD and have been factored into revascularization recommendations. Use of a Heart Team approach has been recommended in cases in which the choice of revascularization is not straightforward. As discussed in Section 2.9.7, the ability of the patient to tolerate and comply with dual antiplatelet therapy (DAPT) is also an important consideration in revascularization decisions.

The 2005 PCI guideline (8) recommended routine angiographic follow-up 2 to 6 months after stenting for unprotected left main CAD. However, because angiography has limited ability to predict stent thrombosis and the results of SYNTAX suggest good intermediate-term results for PCI in subjects with left main CAD, this recommen-

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

dation was removed in the 2009 STEMI/PCI focused update (10).

Experts have recommended immediate PCI for unprotected left main CAD in the setting of STEMI (51). The impetus for such a strategy is greatest when left main CAD is the site of the culprit lesion, antegrade coronary flow is diminished (e.g., TIMI flow grade 0, 1, or 2), the patient is hemodynamically unstable, and it is believed that PCI can be performed more quickly than CABG. When possible, the interventional cardiologist and cardiac surgeon should decide together on the optimal form of revascularization for these subjects, although it is recognized that these patients are usually critically ill and therefore not amenable to a prolonged deliberation or discussion of treatment options.

2.8. Proximal LAD Artery Disease

A cohort study (53) and a meta-analysis (30) from the 1990s suggested that CABG confers a survival advantage over contemporaneous medical therapy for patients with disease in the proximal segment of the LAD artery. Cohort studies and RCTs (30,133,146,148,161,178–181) as well as collaborative- and meta-analyses (164,182–184) showed that PCI and CABG result in similar survival rates in these patients.

See Online Data Supplement 13 for additional data regarding proximal LAD artery revascularization.

2.9. Clinical Factors That May Influence the Choice of Revascularization

2.9.1. Diabetes Mellitus

An analysis performed in 2009 of data on 7,812 patients (1,233 with diabetes) in 10 RCTs demonstrated a worse long-term survival rate in patients with diabetes mellitus after balloon angioplasty or BMS implantation than after CABG (164). The BARI 2D trial (116) randomly assigned 2,368 patients with type 2 diabetes and CAD to undergo intensive medical therapy or prompt revascularization with PCI or CABG, according to whichever was thought to be more appropriate. By study design, those with less extensive CAD more often received PCI, whereas those with more extensive CAD were more likely to be treated with CABG. The study was not designed to compare PCI with CABG. At 5-year follow-up, no difference in rates of survival or MACE between the medical therapy group and those treated with revascularization was noted. In the PCI stratum, no significant difference in MACE between medical therapy and revascularization was demonstrated (DES in 35%; BMS in 56%); in the CABG stratum, MACE occurred less often in the revascularization group. One-year follow-up data from the SYNTAX study demonstrated a higher rate of repeat revascularization in patients with diabetes mellitus treated with PCI than with CABG, driven by a tendency for higher repeat revascularization rates in those with higher SYNTAX scores undergoing PCI (76). In summary, in subjects requiring revascularization for multivessel CAD, current evidence supports diabetes mellitus as an important factor when deciding on a revascularization strategy, particularly when complex or extensive CAD is present (Figure 2).

See Online Data Supplements 14 and 15 for additional data regarding diabetes mellitus.

2.9.2. Chronic Kidney Disease

Cardiovascular morbidity and mortality rates are markedly increased in patients with chronic kidney disease (CKD) when compared with age-matched controls without CKD. The mortality rate for patients on hemodialysis is >20% per year, and approximately 50% of deaths among these patients are due to a cardiovascular cause (187,188).

To date, randomized comparisons of coronary revascularization (with CABG or PCI) and medical therapy in patients with CKD have not been reported. Some, but not all, observational studies or subgroup analyses have demonstrated an improved survival rate with revascularization compared with medical therapy in patients with CKD and multivessel CAD (189–191), despite the fact that the incidence of periprocedural complications (e.g., death, MI, stroke, infection, renal failure) is increased in patients with CKD compared with those without renal dysfunction. Some studies have shown that CABG is associated with a greater survival benefit than PCI among patients with severe renal dysfunction (190–196).

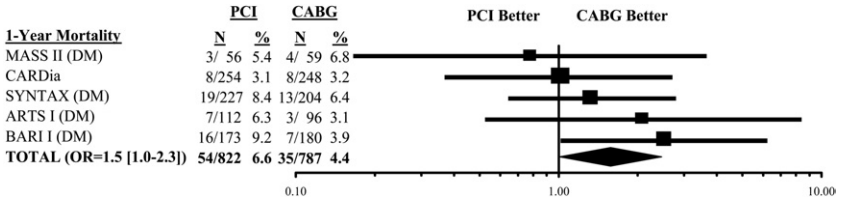

Figure 2. 1-Year Mortality After Revascularization for Multivessel Disease and Diabetes Mellitus

ARTICLE IN PRESS

2.9.3. Completeness of Revascularization

Most patients undergoing CABG receive complete or nearly complete revascularization, which seems to influence long-term prognosis positively (197). In contrast, complete revascularization is accomplished less often in subjects receiving PCI (e.g., in <70% of patients), but the extent to which the absence of complete initial revascularization influences outcome is less clear. Rates of late survival and survival free of MI appears to be similar in patients with and without complete revascularization after PCI. Nevertheless, the need for subsequent CABG is usually higher in those whose initial revascularization procedure was incomplete (compared with those with complete revascularization) after PCI (198–200).

2.9.4. LV Systolic Dysfunction

Several older studies and a meta-analysis of the data from these studies reported that patients with LV systolic dysfunction (predominantly mild to moderate in severity) had better survival with CABG than with medical therapy alone (30,64–68). For patients with more severe LV systolic dysfunction, however, the evidence that CABG results in better survival compared with medical therapy is lacking. In the STICH (Surgical Treatment for Ischemic Heart Failure) trial of subjects with LVEF <35% with or without viability testing, CABG and GDMT resulted in similar rates of survival (death from any cause, the study's primary outcome) after 5 years of follow-up. For a number of secondary outcomes at this time point, including 1) death from any cause or hospitalization for heart failure, 2) death from any cause or hospitalization for cardiovascular causes, 3) death from any cause or hospitalization for any cause, or 4) death from any cause or revascularization with PCI or CABG, CABG was superior to GDMT. Although the primary outcome (death from any cause) was similar in the 2 treatment groups after an average of 5 years of follow-up, the data suggest the possibility that outcomes would differ if the follow-up were longer in duration; as a result, the study is being continued to provide follow-up for up to 10 years (83,84).

Only very limited data comparing PCI with medical therapy in patients with LV systolic dysfunction are available (68). In several ways, these data are suboptimal, in that many studies compared CABG with balloon angioplasty, many were retrospective, and many were based on cohort or registry data. Some of the studies demonstrated a similar survival rate in patients having CABG and PCI (71,164,201–203), whereas others showed that those undergoing CABG had better outcomes (32). The data that exist at present on revascularization in patients with CAD and LV systolic dysfunction are more robust for CABG than for PCI, although data from contemporary RCTs in this patient population are lacking. Therefore, the choice of revascularization in patients with CAD and LV systolic dysfunction is best based on clinical variables (e.g., coronary anatomy, presence of diabetes mellitus, presence of CKD), magnitude of LV systolic dysfunction, patient preferences, clinical judgment, and consultation between the interventional cardiologist and the cardiac surgeon.

2.9.5. Previous CABG

In patients with recurrent angina after CABG, repeat revascularization is most likely to improve survival in subjects at highest risk, such as those with obstruction of the proximal LAD artery and extensive anterior ischemia (85–93). Patients with ischemia in other locations and those with a patent LIMA to the LAD artery are unlikely to experience a survival benefit from repeat revascularization (92).

Cohort studies comparing PCI and CABG among post-CABG patients report similar rates of mid- and long-term survival after the 2 procedures (85,88–91,93,204). In the patient with previous CABG who is referred for revascularization for medically refractory ischemia, factors that may support the choice of repeat CABG include vessels unsuitable for PCI, number of diseased bypass grafts, availability of the internal mammary artery for grafting chronically occluded coronary arteries, and good distal targets for bypass graft placement. Factors favoring PCI over CABG include limited areas of ischemia causing symptoms, suitable PCI targets, a patent graft to the LAD artery, poor CABG targets, and comorbid conditions.

2.9.6. Unstable Angina/Non–ST-Elevation Myocardial Infarction

The main difference between management of the patient with SIHD and the patient with UA/NSTEMI is that the impetus for revascularization is stronger in the setting of UA/NSTEMI, because myocardial ischemia occurring as part of an ACS is potentially life threatening, and associated anginal symptoms are more likely to be reduced with a revascularization procedure than with GDMT (205–207). Thus, the indications for revascularization are strengthened by the acuity of presentation, the extent of ischemia, and the ability to achieve full revascularization. The choice of revascularization method is generally dictated by the same considerations used to decide on PCI or CABG for patients with SIHD.

2.9.7. DAPT Compliance and Stent Thrombosis: Recommendation

CLASS III: HARM

1. **PCI with coronary stenting (BMS or DES) should not be performed if the patient is not likely to be able to tolerate and comply with DAPT for the appropriate duration of treatment based on the type of stent implanted (208–211).** ***(Level of Evidence: B)***

The risk of stent thrombosis is increased dramatically in patients who prematurely discontinue DAPT, and stent thrombosis is associated with a mortality rate of 20% to 45% (208). Because the risk of stent thrombosis with BMS is greatest in the first 14 to 30 days, this is the generally

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

recommended minimum duration of DAPT therapy for these individuals. Consensus in clinical practice is to treat DES patients for at least 12 months with DAPT to avoid late (after 30 days) stent thrombosis (208,212). Therefore, the ability of the patient to tolerate and comply with at least 30 days of DAPT with BMS treatment and at least 12 months of DAPT with DES treatment is an important consideration in deciding whether to use PCI to treat patients with CAD.

2.10. TMR as an Adjunct to CABG

TMR has been used on occasion in patients with severe angina refractory to GDMT in whom complete revascularization cannot be achieved with PCI and/or CABG. Although the mechanism by which TMR might be efficacious in these patients is unknown (213,214), several RCTs of TMR as sole therapy demonstrated a reduction in anginal symptoms compared with intensive medical therapy alone (109–111,215–217). A single randomized multicenter comparison of TMR (with a holmium:YAG laser) plus CABG and CABG alone in patients in whom some myocardial segments were perfused by arteries considered not amenable to grafting (112) showed a significant reduction in perioperative mortality rate (1.5% versus 7.6%, respectively), and the survival benefit of the TMR–CABG combination was present after 1 year of follow-up (112). At the same time, a large retrospective analysis of data from the STS National Cardiac Database as well as a study of 169 patients from the Washington Hospital Center who underwent combined TMR–CABG, showed no difference in adjusted mortality rate compared with CABG alone (113,218). In short, a TMR–CABG combination does not appear to improve survival compared with CABG alone. In selected patients, however, such a combination may be superior to CABG alone in relieving angina.

2.11. Hybrid Coronary Revascularization: Recommendations

CLASS IIa

1. Hybrid coronary revascularization (defined as the planned combination of LIMA-to-LAD artery grafting and PCI of ≥1 non-LAD coronary arteries) is reasonable in patients with 1 or more of the following (219–225) *(Level of Evidence: B)*:
   a. Limitations to traditional CABG, such as heavily calcified proximal aorta or poor target vessels for CABG (but amenable to PCI);
   b. Lack of suitable graft conduits;
   c. Unfavorable LAD artery for PCI (i.e., excessive vessel tortuosity or CTO).

CLASS IIb

1. Hybrid coronary revascularization (defined as the planned combination of LIMA-to-LAD artery grafting and PCI of ≥1 non-LAD coronary arteries) may be reasonable as an alternative to multivessel PCI or CABG in an attempt to improve the overall risk-benefit ratio of the procedures. *(Level of Evidence: C)*

Hybrid coronary revascularization, defined as the planned combination of LIMA-to-LAD artery grafting and PCI of ≥1 non-LAD coronary arteries (226), is intended to combine the advantages of CABG (i.e., durability of the LIMA graft) and PCI (227). Patients with multivessel CAD (e.g., LAD and ≥1 non-LAD stenoses) and an indication for revascularization are potentially eligible for this approach. Hybrid revascularization is ideal in patients in whom technical or anatomic limitations to CABG or PCI alone may be present and for whom minimizing the invasiveness (and therefore the risk of morbidity and mortality) of surgical intervention is preferred (221) (e.g., patients with severe preexisting comorbidities, recent MI, a lack of suitable graft conduits, a heavily calcified ascending aorta, or a non-LAD coronary artery unsuitable for bypass but amenable to PCI, and situations in which PCI of the LAD artery is not feasible because of excessive tortuosity or CTO).

Hybrid coronary revascularization may be performed in a hybrid suite in one operative setting or as a staged procedure (i.e., PCI and CABG performed in 2 different operative suites, separated by hours to 2 days, but typically during the same hospital stay). Because most hospitals lack a hybrid operating room, staged procedures are usually performed. With the staged procedure, CABG before PCI is preferred, because this approach allows the interventional cardiologist to 1) verify the patency of the LIMA-to-LAD artery graft before attempting PCI of other vessels and 2) minimize the risk of perioperative bleeding that would occur if CABG were performed after PCI (i.e., while the patient is receiving DAPT). Because minimally invasive CABG may be associated with lower graft patency rates compared with CABG performed through a midline sternotomy, it seems prudent to angiographically image all grafts performed through a minimally invasive approach to confirm graft patency (221).

To date, no RCTs involving hybrid coronary revascularization have been published. Over the past 10 years, several small, retrospective series of hybrid revascularization using minimally invasive CABG and PCI have reported low mortality rates (0 to 2%) and event-free survival rates of 83% to 92% at 6 to 12 months of follow-up. The few series that have compared the outcomes of hybrid coronary revascularization with standard CABG report similar outcomes at 30 days and 6 months (219–225).

3. PCI Outcomes

3.1. Definitions of PCI Success

The success of a PCI procedure is best defined by 3 interrelated components: angiographic findings, procedural events, and clinical outcomes.

3.1.1. Angiographic Success

A successful PCI produces sufficient enlargement of the lumen at the target site to improve coronary artery blood flow. A successful balloon angioplasty is defined as the reduction of a minimum stenosis diameter to <50% with a final TIMI flow grade 3 (visually assessed by angiography)

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

without side branch loss, flow-limiting dissection, or angiographic thrombus (7). For coronary stents, a minimum stenosis diameter of <20% (as visually assessed by angiography) has previously been the clinical benchmark of an optimal angiographic result. Given improvements in technology and techniques, as well as recognition of the importance of an adequately deployed stent to decrease the risks of stent restenosis and thrombosis (12,228,229), the writing committee concluded that a minimum diameter stenosis of <10% (with an optimal goal of as close to 0% as possible) should be the new benchmark for lesions treated with coronary stenting. As with balloon angioplasty, there should be final TIMI flow grade 3, without occlusion of a significant side branch, flow-limiting dissection, distal embolization, or angiographic thrombus. Problems with determining angiographic success include disparities between the visual assessment and computer-aided quantitative stenosis measurement and self-reporting of success in clinical reports or databases.

3.1.2. Procedural Success

A successful PCI should achieve angiographic success without associated in-hospital major clinical complications (e.g., death, MI, stroke, emergency CABG) (7,8). Issues regarding the diagnosis and prognostic implications of procedure-related MI are discussed in Sections 3.3 and 5.10.

3.1.3. Clinical Success

In the short term, a clinically successful PCI requires both anatomic and procedural success along with relief of signs and/or symptoms of myocardial ischemia. Long-term clinical success requires that the short-term clinical success remain durable and that relief of signs and symptoms of myocardial ischemia persist >9 months after the procedure. Restenosis is the principal cause of lack of long-term clinical success after a short-term clinical success has been achieved. Restenosis is not a complication; it is the expected biological response to vascular injury. The frequency of clinically important restenosis may be judged by the frequency with which subsequent revascularization procedures are performed on target arteries after the index procedure.

3.2. Predictors of Clinical Outcome After PCI

Factors associated with increased PCI complication rates include advanced age, diabetes, CKD, ACS, congestive heart failure, and multivessel CAD (8,230–232). Several models have been developed and refined over the past 2 decades to predict mortality with PCI (230,233–236). At present, perhaps the best accepted system is from the ACC National Cardiovascular Data Registry (NCDR) CathPCI Risk Score system, which uses clinical variables and PCI setting to predict inpatient mortality (Appendix 4A) (236). In general, these models perform very well (C statistic: approximately 0.90), although predictive capability decreases in high-risk patients.

Models have also been developed to predict procedural success. Presently, the modified ACC/AHA score (230) and the SCAI score (Appendix 4B) (237) are both in use, with the latter slightly outperforming the former. Discrimination as measured by the C statistic is generally good to very good (0.70 to 0.82), depending on the outcome variable and patient population.

The angiographic SYNTAX score (238) has been developed to predict long-term risk of MACE after multivessel intervention. The SYNTAX score and its potential utility in helping guide revascularization strategies are discussed in Section 2. Composite models including angiographic and clinical variables have been developed but generally require validation in larger cohorts of patients.

3.3. PCI Complications

In an analysis of the NCDR CathPCI database of patients undergoing PCI between 2004 and 2007, the overall in-hospital mortality rate was 1.27%, ranging from 0.65% in elective PCI to 4.81% in STEMI (236). Factors associated with an increased risk of PCI-related death include advanced age, comorbidities (e.g., diabetes, CKD, congestive heart failure), multivessel CAD, high-risk lesions, and the setting of PCI (e.g., STEMI, urgent or emergency procedure, cardiogenic shock) (56,230–232,236).

Causes of procedural and periprocedural MI include acute artery closure, embolization and no-reflow, side branch occlusion, and acute stent thrombosis. The incidence of procedure-related MI depends to a great degree on the definition of MI used, the patient population studied, and whether or not cardiac biomarkers are routinely assessed after PCI. The definition and clinical significance of PCI-related MI have been controversial. Criteria for defining a PCI-related MI have evolved over time (8,239,240). The 2007 universal definition of MI (240) states that after PCI, elevations of cardiac biomarkers above the 99th percentile upper reference limit indicate periprocedural myocardial necrosis. Increases of biomarkers >3 times the 99th percentile upper reference limit were designated as defining PCI-related MI (240). According to this definition, ≥15% of patients undergoing PCI would be defined as having periprocedural MI (241,242). Issues in procedure-related MI are discussed in Section 5.10.

The need for emergency CABG has dramatically decreased with advances in PCI technology, particularly coronary stents (243,244). Recently the NCDR reported the rate of emergency CABG at 0.4% (244). Procedure-related indications for CABG in 1 large series included coronary dissection (27%), acute artery closure (16%), perforation (8%), and failure to cross the lesion (8%) (245). The strongest predictors of the need for emergency CABG in several analyses are cardiogenic shock (OR: 11.4), acute MI or emergency PCI (OR: 3.2 to 3.8), multivessel disease (OR: 2.3 to 2.4), and type C lesion (OR: 2.6) (243,245). In-hospital mortality for emergency CABG ranges from 7.8% to 14% (243,245,246).

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

In a contemporary analysis from the NCDR, the incidence of PCI-related stroke was 0.22% (247). In-hospital mortality in patients with PCI-related stroke is 25% to 30% (247,248). Factors associated with an increased risk of stroke include fibrinolytic therapy administered before PCI (OR: 4.7), known cerebrovascular disease (OR: 2.20), STEMI as the indication for PCI (OR: 3.2), use of an intra-aortic balloon pump (IABP) (OR: 2.6), older age (OR: 1.17 per 5-year increase), and female sex (247–249). Initial imaging after a stroke in 1 small series revealed hemorrhagic etiology in 18%, ischemic etiology in 58%, and no clear etiology in 24% (248). One potential algorithm for the treatment of catheterization-related stroke has been recently proposed (250). This document includes no specific recommendations for the management of PCI-related stroke but refers the reader to the AHA/American Stroke Association guidelines for the management of adults with stroke (251).

Vascular complications from PCI are primarily related to vascular access. Important femoral vascular complications include access site hematoma, retroperitoneal hematoma, pseudoaneurysm, arteriovenous fistula, and arterial dissection and/or occlusion (252). The incidence of these vascular complications in various reports generally ranges from 2% to 6% and has decreased with time (249,253–257). Factors associated with an increased risk of vascular complication include age ≥70 years, body surface area <1.6 m^2, emergency procedures, peripheral artery disease, periprocedural use of glycoprotein (GP) IIb/IIIa inhibitors, and female sex (if not corrected for body surface area) (249,253,254,257,258). Ultrasound guidance has been used for femoral artery access to potentially decrease complications (259). As discussed in Section 5.11, vascular closure devices have not been clearly demonstrated to decrease vascular complication rates. Radial site access decreases the rate of access-related bleeding and complications compared with femoral access (255,260). Loss of the radial pulse has been reported in ≤5% of radial procedures (261). Infrequent to rare complications occurring with the radial artery approach include compartment syndrome, pseudoaneurysm (<0.01%), and sterile abscess (occurring with previous-generation hydrophilic sheaths) (262). Radial artery spasm may occur and treatment at times may be challenging. Local hematomas may occur from small-branch vessel hydrophilic wire perforation or inexperience with wristband use.

The risk of coronary perforation is approximately 0.2%, most commonly by wire perforation during PCI for CTO or by ablative or oversized devices during PCI of heavily diseased or tortuous coronary arteries (263). The risk of tamponade and management of the perforation varies with the type of perforation (264).

Periprocedural bleeding is now recognized to be associated with subsequent mortality (265,266), and the avoidance of bleeding complications has become an important consideration in performing PCI. The risk of bleeding is associated with patient factors (e.g., advanced age, low body mass index, CKD, baseline anemia), as well as the degree of platelet and thrombin inhibition, vascular access site, and sheath size (267–269). Issues of periprocedural bleeding are discussed in Section 4.7.

The incidence of contrast-induced acute kidney injury (AKI) or "contrast nephropathy" in published reports depends on the definition of contrast nephropathy used and the frequency of risk factors for contrast-induced AKI in the patient population studied. Important risk factors for contrast-induced AKI include advanced age, CKD, congestive heart failure, diabetes, and the volume of contrast administered. Contrast-induced AKI and strategies to prevent it are discussed in Section 4.4.

4. Preprocedural Considerations

Table 4 contains recommendations for preprocedural considerations and interventions in patients undergoing PCI.

4.1. Cardiac Catheterization Laboratory Requirements

4.1.1. Equipment

Defibrillators are considered by The Joint Commission to be life-support equipment requiring routine assessment and completion of appropriate logs. Many hospitals require periodic inspection of consoles for ancillary devices used in coronary intervention (e.g., Doppler wires, pressure-tipped sensor wires, and IVUS catheters). Point-of-care testing devices (e.g., activated clotting time and arterial blood gas machines) require routine calibration. Duration of storage of digital cine images is often mandated by law. Operating parameters for x-ray imaging equipment are adjusted at installation and periodically assessed by a qualified physicist in cooperation with the equipment manufacturer. Familiarity with radiation dose–reducing features of catheterization laboratory equipment and assistance from a qualified physicist are important for radiation dose minimization and image optimization.

4.1.2. Staffing

An interventional cardiologist must be present in the laboratory for the duration of each procedure and is responsible for procedure outcome. Nursing and technical personnel are also required to be present in the catheterization laboratory, with specific staffing dependent on state requirements and laboratory caseload and mix. Catheterization laboratory technical staff may include nurse practitioners, registered nurses, licensed vocational or practical nurses, physician assistants, nursing assistants, radiology technicians, or catheterization laboratory technicians. All catheterization laboratory staff are usually certified in basic life support, advanced cardiovascular life support, and, where appropriate, pediatric advanced life support. Catheterization laboratory personnel have a nursing degree/certification or invasive cardiovascular credentials such as registered cardio-

Table 4. Summary of Recommendations for Preprocedural Considerations and Interventions in Patients Undergoing PCI

Recommendations	COR	LOE	References
Contrast-induced AKI			
Patients should be assessed for risk of contrast-induced AKI before PCI.	I	C	(270,271)
Patients undergoing cardiac catheterization with contrast media should receive adequate preparatory hydration.	I	B	(272–275)
In patients with CKD (creatinine clearance <60 mL/min), the volume of contrast media should be minimized.	I	B	(276–278)
Administration of N-acetyl-L-cysteine is not useful for the prevention of contrast-induced AKI.	III: No Benefit	A	(279–283)
Anaphylactoid reactions			
Patients with prior evidence of an anaphylactoid reaction to contrast media should receive appropriate prophylaxis before repeat contrast administration.	I	B	(252,284–286)
In patients with a prior history of allergic reactions to shellfish or seafood, anaphylactoid prophylaxis for contrast reaction is not beneficial.	III: No Benefit	C	(287–289)
Statins			
Administration of a high-dose statin is reasonable before PCI to reduce the risk of periprocedural MI.	IIa	A: Statin naïve	(290–296)
		B: Chronic statin therapy	(297)
Bleeding risk			
All patients should be evaluated for risk of bleeding before PCI.	I	C	N/A
CKD			
In patients undergoing PCI, the glomerular filtration rate should be estimated and the dosage of renally cleared medications should be adjusted.	I	B	(298–300)
Aspirin			
Patients already on daily aspirin therapy should take 81 mg to 325 mg before PCI.	I	B	(301–304)
Patients not on aspirin therapy should be given nonenteric aspirin 325 mg before PCI.	I	B	(301,303,304)

AKI indicates acute kidney injury; CKD, chronic kidney disease; COR, class of recommendation; LOE, level of evidence; MI, myocardial infarction; N/A, not applicable; and PCI, percutaneous coronary intervention.

vascular invasive specialist or American Society of Radiation technologists (305).

4.1.3. 'Time-Out' Procedures

In 2003, The Joint Commission mandated a universal protocol requiring proper preoperative identification of the patient by the members of the catheterization laboratory team, marking of the operative site, and a final time-out just before the procedure (306). Although initially intended to prevent wrong-site surgery, this has been expanded to include all invasive procedures despite limited scientific evidence of its effectiveness (307). The intent of the time-out is for all members of the team to improve patient care by collectively discussing the case. The content of a time-out includes confirmation of the correct patient, correct side and site, agreement on the procedure to be performed, correct patient position, and availability of needed equipment, supplies, and implants. The time-out may be checklist driven or conversational, depending on laboratory preferences (308). The writing committee strongly endorses the practice of conducting a time-out before all PCI procedures.

4.2. Ethical Aspects

The 3 principles of medical ethics are beneficence, autonomy, and justice. Beneficence involves the physician's duty to act in the best interests of the patient and avoid maleficence, or harm (*primum non nocere*). Autonomy describes the physician's duty to help the patient maintain control over his or her medical treatments. Justice describes the physician's duty to treat the individual patient responsibly with due consideration of other patients and stakeholders in the healthcare system. Ethical considerations specific to PCI have been previously discussed (309) and are highlighted below:

- Place the patient's best interest first and foremost when making clinical decisions (beneficence).
- Ensure that patients actively participate in decisions affecting their care (autonomy).
- Consider how decisions regarding one patient may also affect other patients and providers (justice).
- Plan and perform procedures and provide care with the intention of improving the patient's quality of life and/or decreasing the risk of mortality, independent of reimbursement considerations and without inappropriate bias or influence from industry, administrators, referring physicians, or other sources.
- Before performing procedures, obtain informed consent after giving an explanation regarding the details of the procedure and the risks and benefits of both the procedure and alternatives to the procedure.
- Plan and perform procedures according to standards of care and recommended guidelines, and deviate from them when appropriate or necessary in the care of individual patients.

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

- Seek advice, assistance, or consultation from colleagues when such consultation would benefit the patient.

4.2.1. Informed Consent

Obtaining informed consent for procedures is a legal and ethical necessity. Ideally, informed consent is obtained long enough before the procedure that the patient can fully consider informed consent issues and discuss them with family or other providers, avoiding any sense of coercion. Ad hoc PCI, or PCI immediately following diagnostic procedures, presents special problems. When informed consent for PCI is obtained before diagnostic catheterization is performed, it is impossible to predict the levels of risk and benefit from an ad hoc PCI (310,311). If diagnostic catheterization reveals anatomy that poses a particularly high risk or for which the superiority of PCI compared with other strategies is unclear, the precatheterization informed consent discussion may be inadequate. In such cases, deferral of PCI until additional informed consent discussions and/or consultations occur may be appropriate, even though it inconveniences the patient and the healthcare system. It is the responsibility of the interventionalist to act in the patient's best interest in these circumstances.

Informed consent before emergency procedures is particularly difficult (312–314). The patient presenting with STEMI is usually in distress and often sedated, making true informed consent impossible. Rapid triage, transport, and treatment of STEMI patients create a pressured atmosphere that by necessity limits a prolonged and detailed informed consent process. Nevertheless, the interventionist must attempt to provide information about the risks and benefits of different strategies to the patient and family and balance the benefit of thorough discussion with the benefits of rapid intervention.

4.2.2. Potential Conflicts of Interest

Decisions about the performance and timing of PCI may pose additional ethical dilemmas. When considering whether to perform multivessel PCI in 1 stage versus 2 stages, safety and convenience for the patient must guide the decision, regardless of payment policies that maximize reimbursement when PCI is staged (311). A separate issue is self-referral, through which diagnostic catheterization often leads seamlessly to PCI by the same operator (315). The interventionist has an ethical obligation to the patient to consider all treatment options, consult with additional specialists (e.g., cardiac surgeons) when their input would be helpful to the patient, avoid unnecessary interventional procedures, and allow the patient to consult family members and other physicians (311).

4.3. Radiation Safety: Recommendation

CLASS I

1. Cardiac catheterization laboratories should routinely record relevant available patient procedural radiation dose data (e.g., total air kerma at the international reference point [$K_{a,r}$], air kerma air product [P_{KA}], fluoroscopy time, number of cine images), and should define thresholds with corresponding follow-up protocols for patients who receive a high procedural radiation dose. *(Level of Evidence: C)*

The issue of radiation exposure during imaging procedures has received increased attention, and the writing committee believes that radiation safety should be addressed in this guideline. Current standards for cardiac catheterization laboratories include the following:

- Specific procedures and policies are in place to minimize patient (and operator) risk.
- A radiation safety officer coordinates all radiation safety issues and works conjointly with the medical or health physicist.
- Patient radiation exposure is reduced to as low a level as reasonably can be achieved.
- Patients at increased risk for high procedural radiation exposure are identified.
- Informed consent includes radiation safety information, particularly for the high-risk patient.

A basic primer on the physics of x-ray imaging, essential to the safe practice of radiation dose management, has been published in an ACCF/AHA/Heart Rhythm Society/SCAI clinical competence statement (316). Appendix 4C summarizes strategies to minimize patient and operator radiation exposure. Adverse radiation effects are now well recognized as infrequent but potentially serious complications of prolonged interventional procedures (317). Fluoroscopic time does not include cine acquisition imaging and is therefore not an accurate measure of patient radiation dose. Total air kerma at the interventional reference point ($K_{a,r,}$ in G_y) and air kerma area product (P_{KA}, in $Gycm^2$) are required to be reported on interventional x-ray systems since 2006. These are useful in the assessment of potential tissue adverse effects or long-term radiation sequelae, respectively, and it is reasonable to include them in the catheterization record at the conclusion of each procedure. Appendix 4D summarizes considerations for patient follow-up based on radiation dose during the procedure (317).

4.4. Contrast-Induced AKI: Recommendations

CLASS I

1. Patients should be assessed for risk of contrast-induced AKI before PCI (270,271). *(Level of Evidence: C)*
2. Patients undergoing cardiac catheterization with contrast media should receive adequate preparatory hydration (272–275). *(Level of Evidence: B)*
3. In patients with CKD (creatinine clearance <60 mL/min), the volume of contrast media should be minimized (276–278). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. Administration of N-acetyl-L-cysteine is not useful for the prevention of contrast-induced AKI (279–283). *(Level of Evidence: A)*

See Online Data Supplements 16 to 18 for additional data regarding contrast–induced AKI.

ARTICLE IN PRESS

Contrast-induced AKI or "contrast nephropathy" is one of the leading causes of hospital-acquired AKI. Major risk factors for contrast-induced AKI include advanced age, CKD, congestive heart failure, diabetes, and the volume of contrast administered. A risk-scoring system is available to predict the risk of contrast nephropathy using these risk factors and additional variables (270). Thus far, the only strategies clearly shown to reduce the risk of contrast-induced AKI are hydration and minimizing the amount of contrast media. Other than saline hydration, measures that were believed to reduce the risk of contrast-induced AKI have been found to be neutral, to have deleterious effects, or to be characterized by heterogeneous and conflicting data.

Studies of hydration to reduce the risk of contrast-induced AKI suggest that isotonic saline is preferable to half isotonic saline, intravenous (IV) hydration is preferable to oral hydration, hydration for hours before and after exposure to contrast media is preferable to a bolus administration of saline immediately before or during contrast media exposure, and administration of isotonic saline alone is preferable to administration of isotonic saline plus mannitol or furosemide (272–275,320). On the basis of these studies, a reasonable hydration regimen would be isotonic crystalloid (1.0 to 1.5 mL/kg per hour) for 3 to 12 hours before the procedure and continuing for 6 to 24 hours after the procedure (272–275,284,320,321).

Prior studies of N-acetyl-L-cysteine and sodium bicarbonate have produced conflicting results. Some, often small, earlier studies suggested benefit, but many other more contemporary studies and meta-analyses found no clear evidence of benefit, and there are potential issues of publication bias and poor methodology issues in several analyses (279–282,322–332). The recently completed largest randomized study on N-acetyl-L-cysteine and contrast nephropathy in patients undergoing angiographic procedures, ACT (Acetylcysteine for Contrast-Induced Nephropathy Trial), demonstrated no benefit in primary or secondary endpoints. An updated meta-analysis using only high-quality trials similarly demonstrated no benefit (283). Taken as a whole, these studies do not support any recommendation for the use of N-acetyl-L-cysteine, they do, however, provide sufficient data to conclude that N-acetyl-L-cysteine does not prevent contrast-induced AKI in patients undergoing angiographic procedures.

The correlation between the volume of contrast media and the risk of contrast-induced AKI has been documented in several studies (276,277). Thus, minimization of contrast media volume is important to prevent contrast-induced AKI in patients undergoing angiography. The volume of contrast already administered during diagnostic catheterization is an important factor when considering possible "ad hoc" PCI.

Comparative studies of different contrast media (e.g., low-osmolar versus iso-osmolar, one agent versus another agent) have produced variable and sometimes contradictory results (334–339). Thus, current data are insufficient to justify specific recommendations about low- and iso-osmolar contrast media. This issue is discussed in detail in the 2011 UA/NSTEMI focused update (340). For a further discussion of contrast media and PCI, the reader is referred to a position statement by the SCAI (284).

4.5. Anaphylactoid Reactions: Recommendations

CLASS I

1. Patients with prior evidence of an anaphylactoid reaction to contrast media should receive appropriate steroid and antihistamine prophylaxis before repeat contrast administration (252,284–286). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. In patients with a prior history of allergic reactions to shellfish or seafood, anaphylactoid prophylaxis for contrast reaction is not beneficial (287–289). *(Level of Evidence: C)*

The incidence of anaphylactoid reactions to contrast media is ≤1%, and the incidence of severe reactions may be as low as 0.04% (284). Limited data suggest that in patients with a history of prior anaphylactoid reaction, the recurrence rate without prophylaxis is in the range of 16% to 44% (341). Adequate pretreatment of patients with prior anaphylactoid reactions reduces the recurrence rate to close to zero (284–286). A regimen of 50 mg of prednisone administered 13 hours, 7 hours, and 1 hour before the procedure (as well as 50 mg of diphenhydramine 1 hour before the procedure) has been shown to reduce the risk of recurrent anaphylactoid reaction (286). In practice, a regimen of 60 mg of prednisone the night before and morning of the procedure (as well as 50 mg of diphenhydramine 1 hour before the procedure) is often used (252). There are minimal data on the "pretreatment" of patients undergoing emergency PCI (342). One group has suggested IV steroids (e.g., 80 mg to 125 mg of methylprednisolone, 100 mg of hydrocortisone sodium succinate), as well as oral or IV diphenhydramine and possible IV cimetidine (284). For a more detailed discussion of issues related to contrast-induced anaphylactoid reactions, the reader is referred to several dedicated discussions on contrast agents (284,341).

There are no data to suggest that those patients with seafood or shellfish allergies are at risk for an anaphylactoid reaction from exposure to contrast media. Iodine does not mediate seafood, shellfish, or contrast media reactions. The common misconception that seafood allergies and contrast reactions are cross-reactions to iodine probably arose from a survey published in 1975 in which 15% of patients with a history of contrast reaction reported a personal history of shellfish allergy, but nearly identical proportions of patients reported allergies to other foods, such as milk and egg, in the same survey (287). Pretreatment of patients with steroids based only on a history of seafood or shellfish allergy has a small but non-zero risk of adverse effect (e.g., hyperglycemia in a patient with diabetes) without any demonstrated benefit (288,289).

ARTICLE IN PRESS

4.6. Statin Treatment: Recommendation

CLASS IIa

1. Administration of a high-dose statin is reasonable before PCI to reduce the risk of periprocedural MI. *(Level of Evidence: A for statin-naïve patients* [290–296]; *Level of Evidence: B for those on chronic statin therapy* [297]*)*

See Online Data Supplement 19 for additional data regarding preprocedural statin treatment.

Statins have long-term benefits in patients with CAD (343,344) and ACS (345,346). The benefits of statins in ACS begin early, before substantial lipid lowering has occurred (345,347), suggesting pleiotropic effects of statins. These might include anti-inflammatory effects, improvement of endothelial function, decrease of oxidative stress, or inhibition of thrombogenic responses (348). Statins were beneficial when pretreatment was started from 7 days to just before PCI (290–297).

4.7. Bleeding Risk: Recommendation

CLASS I

1. All patients should be evaluated for risk of bleeding before PCI. *(Level of Evidence: C)*

Periprocedural bleeding is now recognized as a major risk factor for subsequent mortality (265,266). Bleeding may lead to mortality directly (because of the bleeding event) or through ischemic complications that occur when antiplatelet or anticoagulant agents are withdrawn in response to the bleeding. Bleeding may also be a marker of comorbidities associated with worse prognosis (e.g., occult cancer). The risk of bleeding is associated with a number of patient factors (e.g., advanced age, low body mass index, CKD, baseline anemia), as well as the degree of platelet and thrombin inhibition, vascular access site, and sheath size (267–269). The overall approach to PCI should be individualized to minimize both ischemic and bleeding risks.

Measures to minimize the risks of bleeding complications are discussed in several sections of this guideline. These include use of anticoagulation regimens associated with a lower risk of bleeding, weight-based dosing of heparin and other agents, use of activated clotting times to guide unfractionated heparin (UFH) dosing, avoidance of excess anticoagulation (349), dosing adjustments in patients with CKD (e.g., eptifibatide, tirofiban, bivalirudin) (350), use of radial artery access site (255), and avoidance of femoral vein cannulation when possible. Vascular closure devices have not been clearly demonstrated to decrease bleeding complications and are discussed in detail in Section 5.11.

4.8. PCI in Hospitals Without On-Site Surgical Backup: Recommendations

CLASS IIa

1. Primary PCI is reasonable in hospitals without on-site cardiac surgery, provided that appropriate planning for program development has been accomplished (351,352). *(Level of Evidence: B)*

CLASS IIb

1. Elective PCI might be considered in hospitals without on-site cardiac surgery, provided that appropriate planning for program development has been accomplished and rigorous clinical and angiographic criteria are used for proper patient selection (352–354). *(Level of Evidence: B)*

CLASS III: HARM

1. Primary or elective PCI should not be performed in hospitals without on-site cardiac surgery capabilities without a proven plan for rapid transport to a cardiac surgery operating room in a nearby hospital or without appropriate hemodynamic support capability for transfer. *(Level of Evidence: C)*

See Online Data Supplement 20 for additional data regarding hospitals without on-site surgical backup.

Primary and elective PCI can be performed at hospitals without on-site cardiac surgical backup with a high success rate, low in-hospital mortality rate, and low rate for emergency CABG (351,353,354). The best outcomes for patients with STEMI are achieved at hospitals with 24/7 access to primary PCI (355). Criteria for the performance of PCI without on-site surgical backup have been proposed in an SCAI expert consensus document (352). Consideration of elective PCI without on-site cardiac surgical backup is thought to be appropriate only when performed by experienced operators with complication rates and outcomes equivalent or superior to national benchmarks. Accurate assessment of complication rates and patient outcomes via a regional or national data registry, so that outcomes can be compared with established benchmarks, is an important quality control component of any PCI program. Desires for personal or institutional financial gain, prestige, market share, or other similar motives are not appropriate considerations for initiation of PCI programs without on-site cardiac surgery. It is only appropriate to consider initiation of a PCI program without on-site cardiac surgical backup if this program will clearly fill a void in the healthcare needs of the community. Competition with another PCI program in the same geographic area, particularly an established program with surgical backup, may not be in the best interests of the community.

Tables 5 and 6 list the SCAI expert consensus document requirements for PCI programs without on-site surgical backup. Table 7 gives the requirements for primary PCI and emergency CABG at hospitals without on-site cardiac surgery, and Table 8 lists the requirements for patient and lesion selection and backup strategy for nonemergency PCI (352).

5. Procedural Considerations

5.1. Vascular Access: Recommendation

CLASS IIa

1. The use of radial artery access can be useful to decrease access site complications (255,260,356–362). *(Level of Evidence: A)*

See Online Data Supplement 21 for additional data regarding radial access.

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Table 5. SCAI Expert Consensus Document Personnel and Facility Requirements for PCI Programs Without On-Site Surgical Backup

Experienced nursing and technical laboratory staff with training in interventional laboratories. Personnel must be comfortable treating acutely ill patients with hemodynamic and electrical instability.
On-call schedule with operation of laboratory 24 h/d, 365 d/y.*
Experienced coronary care unit nursing staff comfortable with invasive hemodynamic monitoring, operation of temporary pacemaker, and management of IABP. Personnel capable of endotracheal intubation and ventilator management both on-site and during transfer if necessary.
Full support from hospital administration in fulfilling the necessary institutional requirements, including appropriate support services (e.g., respiratory care, blood bank).
Written agreements for emergency transfer of patients to a facility with cardiac surgery. Transport protocols should be developed and tested a minimum of 2 times per year.
Well-equipped and maintained cardiac catheterization laboratory with high-resolution digital imaging capability and IABP equipment compatible with transport vehicles. The capability for real-time transfer of images and hemodynamic data (via T-1 transmission line) as well as audio and video images to review terminals for consultation at the facility providing surgical backup support is ideal.
Appropriate inventory of interventional equipment, including guide catheters, balloons, and stents in multiple sizes; thrombectomy and distal protection devices; covered stents; temporary pacemakers; and pericardiocentesis trays. Pressure wire device and IVUS equipment are optimal but not mandatory. Rotational or other atherectomy devices should be used cautiously in these facilities because of the greater risk of perforation.
Meticulous clinical and angiographic selection criteria for PCI (Tables 6 and 7).
Performance of primary PCI as the treatment of first choice for STEMI to ensure streamlined care paths and increased case volumes. Door-to-balloon times should be tracked, and <90 min outlier cases should be carefully reviewed for process improvement opportunities.
On-site rigorous data collection, outcomes analysis, benchmarking, quality improvement, and formalized periodic case review.
Participation in a national data registry where available, such as the ACC NCDR in the United States.

*Required for U.S. facilities but may not be possible for all facilities worldwide.
ACC indicates American College of Cardiology; IABP, intra-aortic balloon pump; IVUS, intravascular ultrasound; NCDR, National Cardiovascular Data Registry; PCI, percutaneous coronary intervention; SCAI, Society for Cardiovascular Angiography and Interventions; and STEMI, ST-elevation myocardial infarction.
Adapted with permission from Dehmer et al. (352).

Femoral artery access remains the most commonly used approach in patients undergoing PCI in the United States. Choosing a femoral artery puncture site is facilitated by fluoroscopic landmark identification or ultrasound guidance. Low punctures have a high incidence of peripheral artery complications, whereas high punctures have an increased risk of retroperitoneal hemorrhage. In patients with a synthetic graft, arterial access is possible after the graft is a few months old and complication rates are not increased (254).

Radial site access is used frequently in Europe and Canada but not in the United States (260). A learning curve exists for the radial approach that will affect procedure time and radiation dose, with a trend toward lower procedural success rates for radial versus femoral access (255). However, compared with femoral access, radial access decreases the rate of access-related bleeding and complications (255,260,363). In a recent large RCT comparing radial and femoral access in patients with ACS undergoing PCI, there was no difference in the primary composite endpoint (death, MI, stroke, major bleeding), although there was a lower rate of vascular complications with the use of radial access (362). Radial artery access is particularly appealing in patients with coagulopathy, elevated international normalized ratio due to warfarin, or morbid obesity.

5.2. PCI in Specific Clinical Situations

5.2.1. UA/NSTEMI: Recommendations

CLASS I

1. An early invasive strategy (i.e., diagnostic angiography with intent to perform revascularization) is indicated in UA/NSTEMI patients who have refractory angina or hemodynamic or electrical instability

Table 6. SCAI Expert Consensus Document Requirements for Off-Site Surgical Backup

1. Interventional cardiologists establish a working relationship with cardiac surgeons at the receiving facility.
2. Cardiac surgeon must have privileges at the referring facility to allow review of treatment options as time allows.
3. Cardiac surgeon and receiving hospital agree to provide cardiac surgical backup for urgent cases at all hours and for elective cases at mutually agreed hours.
4. Surgeon and receiving facility ensure that patients will be accepted based on medical condition, capacity of surgeon to provide services at the time of request, and availability of resources. If this cannot be ensured before the start of an elective procedure, the case should not be done at this time.
5. Interventional cardiologists must review with surgeons the immediate needs and status of any patient transferred for urgent surgery.
6. Hospital administrations from both facilities endorse transfer agreement.
7. Transferring and receiving facilities establish a rigorous protocol for rapid transfer of patients, including the proper personnel with appropriate experience.
8. A transport provider is available to begin transport within 20 min of the request and provide vehicle/helicopter with necessary life-sustaining equipment, including IABP and monitoring capability.
9. Transferring physician obtains consent for surgery from patient or appropriate surrogate.
10. Initial informed consent for PCI discloses that the procedure is being done without on-site surgical backup and acknowledges the possibility of risks related to transfer. The consent process should include the risk of urgent surgery (approximately 0.3%) and state that a written plan for transfer exists.
11. As part of the local continuous quality improvement program, a regular review of all patients transferred for emergency surgery with the outcome of surgery and identification of any improvement opportunities.

IABP indicates intra-aortic balloon pump; PCI, percutaneous coronary intervention; and SCAI, Society for Cardiovascular Angiography and Interventions.
Adapted with permission from Dehmer et al. (352).

ARTICLE IN PRESS

Table 7. SCAI Expert Consensus Document Requirements for Primary PCI and Emergency Aortocoronary Bypass Surgery at Hospitals Without On-Site Cardiac Surgery

Avoid intervention in patients with

- >50% diameter stenosis of left main artery proximal to infarct-related lesion, especially if the area in jeopardy is relatively small and overall LV function is not severely impaired
- Long, calcified, or severely angulated target lesions at high risk for PCI failure with TIMI flow grade 3 present during initial diagnostic angiography
- Lesions in other than the infarct artery (unless they appeared to be flow limiting in patients with hemodynamic instability or ongoing symptoms)
- Lesions with TIMI flow grade 3 that are not amenable to stenting in patients with left main or 3-vessel disease that will require coronary bypass surgery
- Culprit lesions in more distal branches jeopardizing only a modest amount of myocardium when there is more proximal disease that could be worsened by attempted intervention

Transfer emergently for coronary bypass surgery patients with

- High-grade left main or 3-vessel coronary disease with clinical or hemodynamic instability after successful or unsuccessful PCI of an occluded vessel and preferably with IABP support
- Failed or unstable PCI result and ongoing ischemia, with IABP support during transfer

IABP indicates intra-aortic balloon pump; LV, left ventricular; PCI, percutaneous coronary intervention; SCAI, Society for Cardiovascular Angiography and Interventions; and TIMI, Thrombolysis In Myocardial Infarction.

Adapted with permission from Dehmer et al. (352).

(without serious comorbidities or contraindications to such procedures) (207,364,365). *(Level of Evidence: B)*

2. An early invasive strategy (i.e., diagnostic angiography with intent to perform revascularization) is indicated in initially stabilized UA/NSTEMI patients (without serious comorbidities or contraindications to such procedures) who have an elevated risk for clinical events (207,365–367). *(Level of Evidence: A)*
3. The selection of PCI or CABG as the means of revascularization in the patient with ACS should generally be based on the same considerations as those without ACS (53,156,207,368). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. An early invasive strategy (i.e., diagnostic angiography with intent to perform revascularization) is not recommended in patients with extensive comorbidities (e.g., liver or pulmonary failure, cancer) in whom *(Level of Evidence: C)*
   a. The risks of revascularization and comorbid conditions are likely to outweigh the benefits of revascularization,
   b. There is a low likelihood of ACS despite acute chest pain, or
   c. Consent to revascularization will not be granted regardless of the findings.

The goals of coronary angiography and revascularization in UA/NSTEMI patients are to reduce the risk of death and MI and provide symptom relief. To improve prognosis, early risk stratification is essential for selection of medical and/or invasive treatment strategies. Indications for revascularization depend on the patient's clinical risk characteristics and coronary anat-

Table 8. SCAI Expert Consensus Document Requirements for Patient and Lesion Selection and Backup Strategy for Nonemergency PCI by Experienced Operators at Hospitals Without On-Site Cardiac Surgery

Patient risk: expected clinical risk in case of occlusion caused by procedure

High patient risk: Patients with any of the following:

- Decompensated congestive heart failure (Killip Class 3) without evidence for active ischemia, recent CVA, advanced malignancy, known clotting disorders
- LVEF <25%
- Left main stenosis (≥50% diameter) or 3-vessel disease unprotected by prior bypass surgery (>70% stenoses in the proximal segment of all major epicardial coronary arteries)
- Single-target lesion that jeopardizes >50% of remaining viable myocardium

Lesion risk: probability that procedure will cause acute vessel occlusion

Increased lesion risk: lesions in open vessels with any of the following characteristics:

- Diffuse disease (>2 cm in length) and excessive tortuosity of proximal segments
- More than moderate calcification of a stenosis or proximal segment
- Location in an extremely angulated segment (>90%)
- Inability to protect major side branches
- Degenerated older vein grafts with friable lesions
- Substantial thrombus in the vessel or at the lesion site
- Any other feature that may, in the operator's judgment, impede successful stent deployment

Aggressive measures to open CTOs are also discouraged because of an increased risk of perforation.

Strategy for surgical backup based on lesion and patient risk:

- **High-risk patients with high-risk lesions** should not undergo nonemergency PCI at a facility without on-site surgery.
- **High-risk patients with non–high-risk lesions:** Nonemergency patients with this profile may undergo PCI, but confirmation that a cardiac surgeon and operating room are immediately available is necessary.
- **Non–high-risk patients with high-risk lesions** require no additional precautions.
- **Non–high-risk patients with non–high-risk lesions** require no additional precautions. Best scenario for PCI without on-site surgery.

CTO indicates chronic total occlusion; CVA, cerebrovascular accident; LVEF, left ventricular ejection fraction; PCI, percutaneous coronary intervention; and SCAI, Society for Cardiovascular Angiography and Interventions.

omy and are in general stronger in the presence of high-risk clinical presentation (e.g., dynamic electrocardiogram [ECG] changes, elevated troponin, high Global Registry of Acute Coronary Events score), recurrent symptoms, threatened viable myocardium, CKD, and larger ischemic burden (Appendix 4E). For choice of revascularization technique, the anatomical considerations are generally those used for stable CAD, although PCI may initially be performed in the index lesion to stabilize the patient (Section 2).

Contemporary studies variably comparing strategies of very early (within hours of admission), early (within 24 hours of admission), and delayed (1 to 7 days after admission) cardiac catheterization and revascularization support a strategy of *early* angiography and revascularization to reduce the risk of recurrent ischemia and MI, particularly among those at high risk (e.g., Global Registry of Acute Coronary Events score >140) (367,369,370), whereas a delayed approach is reasonable in low-intermediate risk patients (based on clinical course). There is no evidence that incremental benefit is derived by angiography and PCI performed within the first few hours of hospital admission (207,367,371–378).

5.2.2. ST-Elevation Myocardial Infarction

5.2.2.1. CORONARY ANGIOGRAPHY STRATEGIES IN STEMI: RECOMMENDATIONS

CLASS I

1. A strategy of immediate coronary angiography with intent to perform PCI (or emergency CABG) in patients with STEMI is recommended for
   a. Patients who are candidates for primary PCI (351,379–382). *(Level of Evidence: A)*
   b. Patients with severe heart failure or cardiogenic shock who are suitable candidates for revascularization (383,384). *(Level of Evidence: B)*

CLASS IIa

1. A strategy of immediate coronary angiography (or transfer for immediate coronary angiography) with intent to perform PCI is reasonable for patients with STEMI, a moderate to large area of myocardium at risk, and evidence of failed fibrinolysis (385,386). *(Level of Evidence: B)*
2. A strategy of coronary angiography (or transfer for coronary angiography) 3 to 24 hours after initiating fibrinolytic therapy with intent to perform PCI is reasonable for hemodynamically stable patients with STEMI and evidence for successful fibrinolysis when angiography and revascularization can be performed as soon as logistically feasible in this time frame (387–391). *(Level of Evidence: A)*

CLASS IIb

1. A strategy of coronary angiography performed before hospital discharge might be reasonable in stable patients with STEMI who did not undergo cardiac catheterization within 24 hours of STEMI onset. *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. A strategy of coronary angiography with intent to perform PCI is not recommended in patients with STEMI in whom the risks of revascularization are likely to outweigh the benefits or when the patient or designee does not want invasive care. *(Level of Evidence: C)*

The historical reperfusion strategies of "primary PCI," "immediate PCI," "rescue PCI," "deferred PCI," "facilitated PCI," and the "pharmacoinvasive strategy" have evolved in parallel with advances in antithrombotic therapy and STEMI prehospital and hospital systems of care. The clinical challenge in primary PCI is achieving rapid time to treatment and increasing patient access to this preferred reperfusion strategy. The clinical challenge in patients treated with fibrinolytic therapy is deciding for whom and when to perform coronary angiography.

In unstable patients (e.g., severe heart failure or cardiogenic shock, hemodynamically compromising ventricular arrhythmias) not treated initially with primary PCI, a strategy of immediate coronary angiography with intent to perform PCI is implemented unless invasive management is considered futile or unsuitable given the clinical circumstances (383,384).

In stable patients treated with fibrinolytic therapy and clinical suspicion of reperfusion failure, a strategy of immediate coronary angiography followed by PCI improves outcome in those at high risk (385,386). Such a strategy is also implemented in patients with evidence for infarct artery reocclusion (Table 9). The clinical diagnosis of failed

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

fibrinolysis is difficult but is best made when there is <50% ST-segment resolution 90 minutes after initiation of therapy in the lead showing the greatest degree of ST-segment elevation at presentation. Given the association between bleeding events and adverse cardiac events, a reasonable approach is to select moderate- and high-risk patients for PCI and treat low-risk patients with medical therapy. ECG and clinical findings of anterior MI or inferior MI with right ventricular involvement or precordial ST-segment depression, as well as ongoing pain, usually predicts increased risk and the greatest potential benefit (392). Conversely, patients with symptom resolution, improving ST-segment elevation, or inferior MI localized to 3 ECG leads probably gain little benefit.

In stable patients treated with fibrinolytic therapy and clinical evidence for successful reperfusion, an early invasive strategy with cardiac catheterization performed within 24 hours decreases reinfarction and recurrent ischemic events (388,390,391). Because of the associated increased bleeding risk, very early (<2 to 3 hours) catheterization after administration of fibrinolytic therapy with intent to perform revascularization should be reserved for patients with evidence of failed fibrinolysis and significant myocardial jeopardy for whom immediate angiography and revascularization would be appropriate (393).

5.2.2.2. PRIMARY PCI OF THE INFARCT ARTERY: RECOMMENDATIONS

CLASS I

1. Primary PCI should be performed in patients within 12 hours of onset of STEMI (379–382). *(Level of Evidence: A)*
2. Primary PCI should be performed in patients with STEMI presenting to a hospital with PCI capability within 90 minutes of first medical contact as a systems goal (394,395). *(Level of Evidence: B)*
3. Primary PCI should be performed in patients with STEMI presenting to a hospital without PCI capability within 120 minutes of first medical contact as a systems goal (396–398). *(Level of Evidence: B)*
4. Primary PCI should be performed in patients with STEMI who develop severe heart failure or cardiogenic shock and are suitable candidates for revascularization as soon as possible, irrespective of time delay (383,384). *(Level of Evidence: B)*
5. Primary PCI should be performed as soon as possible in patients with STEMI and contraindications to fibrinolytic therapy with ischemic symptoms for less than 12 hours (399,400). *(Level of Evidence: B)*

CLASS IIa

1. Primary PCI is reasonable in patients with STEMI if there is clinical and/or electrocardiographic evidence of ongoing ischemia between 12 and 24 hours after symptom onset (401–403). *(Level of Evidence: B)*

CLASS IIb

1. Primary PCI might be considered in asymptomatic patients with STEMI and higher risk presenting between 12 and 24 hours after symptom onset. *(Level of Evidence: C)*

CLASS III: HARM

1. PCI should not be performed in a noninfarct artery at the time of primary PCI in patients with STEMI without hemodynamic compromise (404–408). *(Level of Evidence: B)*

Primary PCI is preferred to fibrinolytic therapy when time-to-treatment delays are short and the patient presents to a high-volume, well-equipped center staffed with expert interventional cardiologists and skilled support staff. Compared with fibrinolytic therapy in RCTs, primary PCI produces higher rates for infarct artery patency, TIMI flow grade 3, and lower rates for recurrent ischemia, reinfarction, emergency repeat revascularization procedures, intracranial hemorrhage, and death (379). Early, successful PCI also greatly decreases the complications of STEMI that result from longer ischemic times or unsuccessful fibrinolytic therapy, allowing earlier hospital discharge and resumption of daily activities. The greatest mortality benefit of primary PCI is in high-risk patients. PCI outcomes may not be as successful with prolonged time-to-treatment or low-volume hospitals and operators (Table 10).

Several reports have shown excellent outcomes for patients with STEMI undergoing interhospital transfer where first medical contact–to-door balloon time modestly exceeded the systematic goal of <90 minutes (396–398,409). In these reports, the referring hospital and the receiving hospital established a transfer protocol that minimized transfer delays, and outcomes were similar to those of direct-admission patients. On the basis of these results, the PCI and STEMI guideline writing committees have modified the first medical contact–to-device time goal from 90 minutes to 120 minutes for interhospital transfer patients (397), while emphasizing that systems should continue to strive for times ≤90 minutes. Hospitals that cannot meet these criteria should use fibrinolytic therapy as their primary reperfusion strategy.

PCI of a noninfarct artery at the time of primary PCI in stable patients is associated with worse clinical outcomes unless the patient is in cardiogenic shock where PCI of a severe stenosis in a coronary artery supplying a large territory of myocardium might improve hemodynamic stability (404,406,408). Delayed PCI can be performed in noninfarct arteries at a later time if clinically indicated (410–412).

5.2.2.3. DELAYED OR ELECTIVE PCI IN PATIENTS WITH STEMI: RECOMMENDATIONS

CLASS IIa

1. PCI is reasonable in patients with STEMI and clinical evidence for fibrinolytic failure or infarct artery reocclusion (385,386). *(Level of Evidence: B)*
2. PCI is reasonable in patients with STEMI and a patent infarct artery 3 to 24 hours after fibrinolytic therapy (390,391). *(Level of Evidence: B)*
3. PCI is reasonable in patients with STEMI who demonstrate ischemia on noninvasive testing (410,411). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Table 10. Indications for PCI in STEMI

Indications	COR	LOE	References
Primary PCI*			
STEMI symptoms within 12 h	I	A	(379–382)
Severe heart failure or cardiogenic shock	I	B	(383,384)
Contraindications to fibrinolytic therapy with ischemic symptoms <12 h	I	B	(399,400)
Clinical and/or electrocardiographic evidence of ongoing ischemia between 12 and 24 h after symptom onset	IIa	B	(401–403)
Asymptomatic patients presenting between 12 and 24 h after symptom onset and higher risk	IIb	C	N/A
Noninfarct artery PCI at the time of primary PCI in patients without hemodynamic compromise	III: Harm	B	(404–408)
Delayed or elective PCI in patients with STEMI			
Clinical evidence for fibrinolytic failure or infarct artery reocclusion	IIa	B	(385,386)
Patent infarct artery 3 to 24 h after fibrinolytic therapy	IIa	B	(390,391)
Ischemia on noninvasive testing	IIa	B	(410,411)
Hemodynamically significant stenosis in a patent infarct artery >24 h after STEMI	IIb	B	(413–417)
Totally occluded infarct artery >24 h after STEMI in a hemodynamically stable asymptomatic patient without evidence of severe ischemia	III: No Benefit	B	(418–420)

*Systems goal of performing primary PCI within 90 min of first medical contact when the patient presents to a hospital with PCI capability (394,395) (*Class I; LOE: B*) and within 120 min when the patient presents to a hospital without PCI capability (396–398) (*Class I; LOE: B*).

COR indicates class of recommendation; LOE, level of evidence; N/A, not applicable; PCI, percutaneous coronary intervention; and STEMI, ST-elevation myocardial infarction.

CLASS IIb

1. PCI of a hemodynamically significant stenosis in a patent infarct artery greater than 24 hours after STEMI may be considered as part of an invasive strategy (413–417). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. PCI of a totally occluded infarct artery greater than 24 hours after STEMI should not be performed in asymptomatic patients with 1- or 2-vessel disease if patients are hemodynamically and electrically stable and do not have evidence of severe ischemia (418–420). *(Level of Evidence: B)*

Studies and meta-analyses suggest potential benefit for PCI in fibrinolytic failure (385,386). In stable patients treated with fibrinolytic therapy and clinical evidence for successful reperfusion, an early invasive strategy with cardiac catheterization performed within 24 hours decreases reinfarction and recurrent ischemic events (388,390,391).

PCI for a hemodynamically significant stenosis in a patent infarct artery >24 hours after STEMI as part of a revascularization strategy improves outcome (410,411,413–417). PCI of an occluded infarct artery 1 to 28 days after MI in asymptomatic patients without evidence of myocardial ischemia has no incremental benefit beyond optimal medical therapy with aspirin, beta blockers, angiotensin-converting enzyme inhibitors, and statins in preserving LV function and preventing subsequent cardiovascular events (418–420). It is important to note that elective PCI of an occluded infarct artery has not been studied in patients with New York Heart Association functional class III or IV heart failure, rest angina, serum creatinine >2.5 mg/dL, left main or 3-vessel CAD, clinical instability, or severe inducible ischemia on stress testing in an infarct zone that is not akinetic or dyskinetic.

5.2.3. Cardiogenic Shock: Recommendations

CLASS I

1. PCI is recommended for patients with acute MI who develop cardiogenic shock and are suitable candidates (384,421–423). *(Level of Evidence: B)*
2. A hemodynamic support device is recommended for patients with cardiogenic shock after STEMI who do not quickly stabilize with pharmacological therapy (384,424–427). *(Level of Evidence: B)*

See Online Data Supplement 22 for additional data regarding cardiogenic shock.

Cardiogenic shock is the leading cause of in-hospital mortality complicating STEMI. Revascularization is the only treatment proven to decrease mortality rates (384,421–423). Although revascularization is almost always accomplished through PCI, selected patients with severe 3-vessel or left main disease can benefit from emergency CABG. Revascularization attempts may be futile and not indicated in cases of severe multiorgan failure (427). Patient selection for revascularization is more important in the elderly, but several observational reports demonstrate acceptable outcomes in patients with few comorbidities and a reasonable potential for survival (428–431). Patients who present to hospitals without PCI capability are usually emergently transported to a PCI center, because mortality without transfer is markedly elevated (432).

5.2.3.1. PROCEDURAL CONSIDERATIONS FOR CARDIOGENIC SHOCK

Patients with cardiogenic shock should receive standard pharmacological therapies, including aspirin, a $P2Y_{12}$ receptor antagonist, and anticoagulation (427,433). Inotropic and vasopressor therapy improves perfusion pressure. Historically, negative inotropes and vasodilators are avoided. IV

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

GP IIb/IIIa inhibitors have been shown to provide benefit in observational studies but not in 1 small RCT (433).

Endotracheal intubation and mechanical ventilation with positive end-expiratory pressure is usually necessary in patients with respiratory failure. Placement of a temporary pacemaker is indicated for patients with bradycardia or high-degree atrioventricular heart block. A pulmonary artery catheter can provide information to dose and titrate inotropes and pressors. Further hemodynamic support is available with IABP counterpulsation or percutaneous LV assist devices, although no data support a reduction in mortality rates (434).

Contrast medium injections should be minimized. Orthogonal angiograms of the left coronary artery and a left anterior oblique angiogram of the right coronary artery are usually sufficient to identify the infarct artery (435). Although most patients undergoing revascularization will receive a stent as part of the procedure, there are conflicting data on the impact of stenting over balloon angioplasty. Some studies reveal lower mortality rates (436–438), whereas others reveal no benefit (439) or higher mortality rates (440). There are no data comparing the choice of BMS versus DES in cardiogenic shock; however, BMS are often used because compliance with long-term DAPT is often unclear in the emergency setting.

In patients with multivessel disease, revascularization of the noninfarct artery may be necessary to maximize myocardial perfusion. Alternatively, in patients with multivessel disease and particularly left main disease, emergency CABG as a primary reperfusion strategy may be preferred (50,441). Refractory cardiogenic shock unresponsive to revascularization may necessitate institution of more intensive cardiac support with a ventricular assist device or other hemodynamic support devices to allow for myocardial recovery or subsequent cardiac transplantation in suitable patients.

5.2.4. Revascularization Before Noncardiac Surgery: Recommendations

CLASS IIa

1. For patients who require PCI and are scheduled for elective noncardiac surgery in the subsequent 12 months, a strategy of balloon angioplasty, or BMS implantation followed by 4 to 6 weeks of DAPT, is reasonable (442–448). *(Level of Evidence: B)*
2. For patients with DES who must undergo urgent surgical procedures that mandate the discontinuation of DAPT, it is reasonable to continue aspirin if possible and restart the $P2Y_{12}$ inhibitor as soon as possible in the immediate postoperative period (444). *(Level of Evidence: C)*

CLASS III: HARM

1. Routine prophylactic coronary revascularization should not be performed in patients with stable CAD before noncardiac surgery (449,450). *(Level of Evidence: B)*
2. Elective noncardiac surgery should not be performed in the 4 to 6 weeks after balloon angioplasty or BMS implantation or the 12 months after DES implantation in patients in whom the $P2Y_{12}$ inhibitor will need to be discontinued perioperatively (208,447, 451,452). *(Level of Evidence: B)*

The 2007 and 2009 ACC/AHA Guidelines on Perioperative Cardiovascular Evaluation and Care for Noncardiac Surgery gave detailed recommendations for the evaluation of patients undergoing noncardiac surgery (444). Patients with evidence of ACS should receive standard therapy, including early revascularization, to minimize the risk of adverse events. Patients with known significant left main or 3-vessel CAD who would otherwise benefit from revascularization in terms of survival or symptomatic relief also generally undergo revascularization before elective noncardiac surgery.

Two RCTs (449,450) found no benefit with routine preoperative revascularization before noncardiac surgery. Noncardiac surgery early after coronary stenting, particularly in the first 4 weeks, is associated with a high risk of stent thrombosis and death (444,446,448). When emergency surgery is necessary, the patient should proceed to surgery without prior PCI. When surgery is required within 30 days and coronary revascularization is required before surgery, many clinicians perform balloon angioplasty alone to avoid the need for DAPT. In situations where preoperative revascularization is required and surgery can be deferred for at least 30 days, many clinicians use BMS and discontinue DAPT after 30 days. If surgery is elective and can be deferred for 1 year, most clinicians would consider DES to reduce the long-term risk of restenosis. A dilemma occurs when a patient has undergone PCI and then unexpectedly requires noncardiac surgery. Many patients can undergo surgery on DAPT, where the risk-benefit ratio will favor continued dual antiplatelet inhibition. If it is necessary to hold $P2Y_{12}$ inhibitor therapy, most clinicians will still continue aspirin uninterrupted during the perioperative period if the bleeding risk is not prohibitive. When the risk of delaying surgery or performing surgery while the patient is on DAPT exceeds the risk of stent thrombosis from stopping DAPT, the $P2Y_{12}$ inhibitor is stopped before surgery and resumed as soon as possible afterward. No $P2Y_{12}$ inhibitor "bridging" strategy (e.g., GP IIb/IIIa inhibitor, antithrombin therapy) has been validated.

5.3. Coronary Stents: Recommendations

CLASS I

1. Before implantation of DES, the interventional cardiologist should discuss with the patient the need for and duration of DAPT and the ability of the patient to comply with and tolerate DAPT (212). *(Level of Evidence: C)*
2. DES are useful as an alternative to BMS to reduce the risk of restenosis in cases in which the risk of restenosis is increased and the patient is likely to be able to tolerate and comply with prolonged DAPT *(Level of Evidence: A for elective PCI* [453,453a,454–456]*; Level of Evidence: C for UA/NSTEMI* (453)*; Level of Evidence: A for STEMI* [453,456–459]).
3. Balloon angioplasty or BMS should be used in patients with high bleeding risk, inability to comply with 12 months of DAPT, or anticipated invasive or surgical procedures within the next 12 months, during which time DAPT may be interrupted (208,460–462). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

CLASS III: HARM

1. **PCI with coronary stenting should not be performed if the patient is not likely to be able to tolerate and comply with DAPT (208–211). *(Level of Evidence: B)***
2. **DES should not be implanted if the patient is not likely to be able to tolerate and comply with prolonged DAPT or this cannot be determined before stent implantation (208,460–462). *(Level of Evidence: B)***

Coronary stent implantation is commonly performed during PCI to prevent recoil, abrupt closure, and late restenosis (463,464). BMS are composed of either stainless steel or cobalt chromium alloys. Because the risk of stent thrombosis is greatest within the first 30 days after implantation, the use of DAPT is required for 30 days after implantation of BMS (208).

In the United States, 4 types of DES are currently approved: sirolimus-eluting stents, paclitaxel-eluting stents, zotarolimus-eluting stents, and everolimus-eluting stents. DES vary according to stent scaffold material and design, drug content, and the polymer used for drug elution; however, several common clinical features are present. First, sirolimus-eluting stents, paclitaxel-eluting stents, and zotarolimus-eluting stents have been demonstrated in RCTs to be associated with a reduced need for repeat revascularization and no increase in death or MI compared with BMS at 4 years' follow-up (465). Everolimus-eluting stents have been demonstrated in RCTs to be associated with a lower need for repeat revascularization than paclitaxel-eluting stents, and, by inference, a lower risk for repeat revascularization than BMS (466,467), with no increase in death or MI at 2-year follow-up (468). Second, each of these stents is presumed to be associated with delayed healing based on pathologic studies and longer periods of risk for thrombosis compared with BMS and require longer duration of DAPT (469). In the RCTs that led to the U.S. Food and Drug Administration (FDA) approval of these stents, the recommended minimum duration of DAPT therapy was 3 to 6 months. Recently, the consensus of clinical practice has been 12 months of DAPT following DES implantation to avoid late (after 30 days) thrombosis (208), based on observational studies of paclitaxel-eluting stents and sirolimus-eluting stents that indicate lower risk of late stent thrombosis with >6 months of therapy (212). Extending DAPT beyond 1 year is considered reasonable by some practitioners based on observational data analysis (212), but RCTs to determine whether longer DAPT is associated with reduction in stent thrombosis risk have not been completed. Finally, DES therapy is more expensive than BMS. Cost-effectiveness analysis has shown a reduction in total cost associated with DES because of avoidance of repeat procedures, yet it may be reasonable to consider use of BMS in patient subsets in which the risk of restenosis is low (470).

This risk-benefit profile is most favorable for DES over BMS when the risk of restenosis with BMS is high (Table 11). Pooled and meta-analyses have demonstrated that in patients with diabetes, use of DES decreases the risk of restenosis compared with BMS (471,472). DES may be more appealing for unprotected left main PCI, given the rate and clinical consequences of restenosis in this location (473–475). The risk of stent thrombosis is higher in populations or lesion types excluded from RCTs of DES (e.g., STEMI, smaller arteries [<2.5 mm diameter], longer lesions, bifurcations) (210,465). Importantly, these features also predict both stent thrombosis (476) and restenosis in BMS (477). The greatest risk of stent thrombosis is within the first year, ranging from 0.7% to 2.0%, depending on patient and lesion complexity. Late stent thrombosis risk after 1 year with DES is observed at a rate of 0.2% to 0.4% per year (210,478).

Table 11. Clinical Situations Associated With DES or BMS Selection Preference

DES Generally Preferred Over BMS (Efficacy Considerations)	BMS Preferred Over DES (Safety Considerations)
• Left main disease • Small vessels • In-stent restenosis • Bifurcations • Diabetes • Long lesions • Multiple lesions • Saphenous vein grafts	• Unable to tolerate or comply with DAPT • Anticipated surgery requiring discontinuation of DAPT within 12 mo • High risk of bleeding

BMS indicates bare-metal stent(s); DAPT, dual antiplatelet therapy; and DES, drug-eluting stent(s).

Compared with balloon angioplasty, routine BMS implantation during primary PCI decreases risk for target-vessel revascularization and possibly reduces MI rates but does not reduce mortality rates (479). More recent primary PCI studies and meta-analyses have demonstrated lower restenosis rates without increased risk of adverse stent outcome with DES compared with BMS. Although stent thrombosis rates in trials of STEMI are higher than in trials of elective PCI, the rates of stent thrombosis are not higher with DES compared with BMS in STEMI (453,456–459).

The greatest risk for DES thrombosis is early discontinuation of DAPT (208,460–462). It is therefore important to determine that the patient will likely be able to tolerate and comply with DAPT before implantation of DES. Therefore, DES should not be used in the presence of financial barriers to continuing prolonged DAPT, social barriers that may limit patient compliance, or medical issues involving bleeding risks or the need for invasive or surgical procedures in the following year that would interrupt antiplatelet therapy. The need for use of long-term warfarin and the associated increased risk of bleeding with long-term "triple therapy" is also a consideration in deciding on DES versus BMS (480).

Patients implanted with most contemporary coronary stents can undergo magnetic resonance imaging (MRI) examination any time after implantation (481,482). The effect of the MRI examination on heating of the drug or polymer coating used in DES is unknown. There is no

ARTICLE IN PRESS

indication for antibiotic prophylaxis before dental or invasive procedures in patients with coronary stents (483).

5.4. Adjunctive Diagnostic Devices

5.4.1. FFR: Recommendation

CLASS IIa

1. FFR is reasonable to assess angiographic intermediate coronary lesions (50% to 70% diameter stenosis) and can be useful for guiding revascularization decisions in patients with SIHD (12,97, 484–486). *(Level of Evidence: A)*

See Online Data Supplement 23 for additional data regarding FFR.

The limitations of coronary angiography for determination of lesion severity have been well described. Angiography may under- or overestimate lesion stenosis. Various physiologic measurements can be made in the catheterization laboratory, including coronary flow reserve and FFR. The correlation of ischemia on stress testing with FFR values of <0.75 has been established in numerous comparative studies with high sensitivity (88%), specificity (100%), positive predictive value (100%), and overall accuracy (93%) (487). The 5-year outcomes for patients with medical therapy based on an FFR >0.75 were superior compared with PCI in the DEFER (Deferral Versus Performance of Balloon Angioplasty in Patients Without Documented Ischemia) study (485). The FAME (Fractional Flow Reserve Versus Angiography for Multivessel Evaluation) study identified the benefit for deferring PCI in patients with multivessel disease and lesion FFR >0.80, with reduced rates of cardiac events at both 1 and 2 years (97,486). Whereas both FFR and IVUS have been used for assessment of intermediate angiographic stenosis with favorable outcomes, FFR may reduce the need for revascularization when compared with IVUS (488). Although IVUS is often considered in the assessment of equivocal left main stenosis, FFR may be similarly effective (484).

5.4.2. IVUS: Recommendations

CLASS IIa

1. IVUS is reasonable for the assessment of angiographically indeterminant left main CAD (489–491). *(Level of Evidence: B)*
2. IVUS and coronary angiography are reasonable 4 to 6 weeks and 1 year after cardiac transplantation to exclude donor CAD, detect rapidly progressive cardiac allograft vasculopathy, and provide prognostic information (492–494). *(Level of Evidence: B)*
3. IVUS is reasonable to determine the mechanism of stent restenosis (495). *(Level of Evidence: C)*

CLASS IIb

1. IVUS may be reasonable for the assessment of non–left main coronary arteries with angiographically intermediate coronary stenoses (50% to 70% diameter stenosis) (489,496,497). *(Level of Evidence: B)*
2. IVUS may be considered for guidance of coronary stent implantation, particularly in cases of left main coronary artery stenting (490,495,498). *(Level of Evidence: B)*
3. IVUS may be reasonable to determine the mechanism of stent thrombosis (495). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. IVUS for routine lesion assessment is not recommended when revascularization with PCI or CABG is not being contemplated. *(Level of Evidence: C)*

IVUS provides a unique coronary artery assessment of lesion characteristics, minimal and maximal lumen diameters, cross-sectional area, and plaque area. Diagnostic uses for IVUS include the assessment of angiographic indeterminant coronary artery stenoses, determination of the mechanism of stent restenosis or thrombosis, and postcardiac transplantation surveillance of CAD (488,490–492,499). For left main coronary artery stenoses, a minimal lumen diameter of <2.8 mm or a minimal lumen area of <6 mm^2 suggests a physiologically significant lesion for which patients may benefit from revascularization. A minimal lumen area >7.5 mm^2 suggests that revascularization may be safely deferred (490). A minimal lumen area between 6 and 7.5 mm^2 requires further physiological assessment, such as measurement of FFR (487,500). For non–left main stenoses, minimal lumen diameter >2.0 mm and minimal lumen area >4.0 mm^2 correlate with low event rates (489). However, in smaller-diameter arteries (minimal lumen area <3.0 mm^2), measurement of FFR may more accurately reflect a significant stenosis (488). Studies correlating IVUS measures with ischemia have not specified the size of coronary arteries for which such correlations are valid (488,489,497).

IVUS assessment after stent thrombosis may serve to identify stent underexpansion or malapposition (499). IVUS is superior to angiography in the early detection of the diffuse, immune-mediated, cardiac allograft vasculopathy; recommendations about the use of IVUS for this purpose were published in 2010 by the International Society of Heart and Lung Transplantation (492). Whereas IVUS has been an important research tool in interventional cardiology, most clinical studies of IVUS have not been able to demonstrate that its routine use results in a reduction of MACE or restenosis rates (498,501,502). IVUS has been inappropriately used in clinical practice to justify implanting stents in mildly diseased segments that may require no intervention (503).

5.4.3. Optical Coherence Tomography

Compared with IVUS, optical coherence tomography has greater resolution (10 to 20 micronmeter axially) but more limited depth of imaging (1 to 1.5 mm) (504,505). Unlike IVUS, optical coherence tomography requires that the artery be perfused with saline solution or crystalloid during image acquisition and therefore does not permit imaging of ostial lesions. Clinical studies have shown low optical coherence tomography complication rates (506,507), similar to those of IVUS (508). The excellent resolution of optical coherence tomography permits detailed in vivo 2-dimensional imaging of plaque morphological characteristics (e.g., calcification, lipid,

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

thrombus, fibrous cap thickness, and plaque ulceration or rupture) (508–510) and evaluation of the arterial response to stent implantation (e.g., stent strut neointimal thickness and apposition) (511–513) and may be of value in clinical research. The appropriate role for optical coherence tomography in routine clinical decision making has not been established.

5.5. Adjunctive Therapeutic Devices

5.5.1. Coronary Atherectomy: Recommendations

CLASS IIa

1. Rotational atherectomy is reasonable for fibrotic or heavily calcified lesions that might not be crossed by a balloon catheter or adequately dilated before stent implantation (514,515). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. Rotational atherectomy should not be performed routinely for de novo lesions or in-stent restenosis (516–519). *(Level of Evidence: A)*

Rotational atherectomy in RCTs was associated with higher rates of MACE at 30 days and no reduction in restenosis. It has a limited role in facilitating the dilation or stenting of lesions that cannot be crossed or expanded with PCI (520,521). Devices for directional coronary atherectomy are no longer marketed in the United States.

5.5.2. Thrombectomy: Recommendation

CLASS IIa

1. Aspiration thrombectomy is reasonable for patients undergoing primary PCI (522–524). *(Level of Evidence: B)*

The benefit of thrombectomy in patients with STEMI appears to be dependent on the type of thrombectomy technique used (522–526). No clinical benefit for routine rheolytic thrombectomy (AngioJet device, MEDRAD Interventional, Minneapolis, MN and Pittsburgh, PA) has been demonstrated in primary PCI (524–526). Two RCTs (522,523) and a meta-analysis (524) support the use of manual aspiration thrombectomy during primary PCI to improve microvascular reperfusion and decrease MACE. It is not known whether a strategy of selective thrombus aspiration in patients with a large thrombus burden might be equivalent to routine thrombus aspiration.

5.5.3. Laser Angioplasty: Recommendations

CLASS IIb

1. Laser angioplasty might be considered for fibrotic or moderately calcified lesions that cannot be crossed or dilated with conventional balloon angioplasty (527). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. Laser angioplasty should not be used routinely during PCI (516,518,528). *(Level of Evidence: A)*

RCTs of laser angioplasty have not demonstrated improved clinical or angiographic PCI outcomes, although some practitioners think that laser angioplasty may be of use in the treatment of lesions that are difficult to dilate with balloon angioplasty (527).

5.5.4. Cutting Balloon Angioplasty: Recommendations

CLASS IIb

1. Cutting balloon angioplasty might be considered to avoid slippage-induced coronary artery trauma during PCI for in-stent restenosis or ostial lesions in side branches (529). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. Cutting balloon angioplasty should not be performed routinely during PCI (516,529,530). *(Level of Evidence: A)*

Although some small, single-center trials have suggested that cutting balloon angioplasty was more efficacious than balloon angioplasty, it was not found to be safer or more effective in several large trials (516,529,531). When balloon dilation is required for in-stent restenosis, however, cutting balloons are less likely to slip and may offer a technical advantage over conventional balloons (529). Scoring balloons have been used by some cardiologists as an alternative to cutting balloons, but no RCTs have been reported (531).

5.5.5. Embolic Protection Devices: Recommendation

CLASS I

1. Embolic protection devices (EPDs) should be used during saphenous vein graft (SVG) PCI when technically feasible (532–535). *(Level of Evidence: B)*

The incidence of MACE doubles in SVG PCI compared with native-artery PCI (536). A distal balloon occlusion EPD decreased the 30-day composite outcome of death, MI, emergency CABG, or target-lesion revascularization (9.6% versus 16.5%) in the only RCT (532). Subsequent noninferiority comparisons have demonstrated similar benefit with proximal occlusion and distal filter EPDs, with benefit limited to reduction in periprocedural MI (534,535) (Section 5.10). Distal EPDs do not improve survival or reinfarction rates in patients undergoing native-artery PCI (524,537).

5.6. Percutaneous Hemodynamic Support Devices: Recommendation

CLASS IIb

1. Elective insertion of an appropriate hemodynamic support device as an adjunct to PCI may be reasonable in carefully selected high-risk patients. *(Level of Evidence: C)*

IABP counterpulsation is frequently used as an adjunct to PCI in hemodynamically unstable patients (538,539). In single-center series, the routine prophylactic use of IABP during PCI in high-risk patients was associated with lower mortality and fewer major complications compared with rescue use of IABP (540,541). In the only RCT in high-risk PCI patients (BCIS-1 [Balloon Pump-Assisted Coronary Intervention Study]) (542), there was no difference in the primary composite outcome between routine and provisional use of IABP. There were also no differences in major secondary endpoints except major procedural complications (e.g., prolonged hypotension, ventricular tachycardia/fibrillation, cardiopulmonary arrest), which were lower in the

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

routine IABP group. Bleeding and access site complication rates tended to be higher in the routine IABP group. The "bailout" rate of IABP insertion in the provisional IABP group was 12%, mostly for procedural hypotension (542). A meta-analysis of IABP therapy in patients with STEMI did not show improved outcomes with the use of IABP (434).

The Impella Recover LP 2.5 System (Abiomed, Aachen, Germany/Danvers, Massachusetts) is a 12.5 Fr catheter that is inserted percutaneously through a 13 Fr femoral artery sheath and placed across the aortic valve into the left ventricle, through which a transaxial blood pump provides flows of up to 2.5 L/min. This has been used in patients with cardiogenic shock (543,544) as well as elective PCI (545). The hemodynamic effects of the Impella 2.5 have been studied in high-risk PCI patients, demonstrating beneficial LV unloading effect (decreased end-diastolic pressure and wall stress) with no change in global or systolic LV function (546). The PROTECT I (A Prospective Feasibility Trial Investigating the Use of the IMPELLA Recover LP 2.5 System in Patients Undergoing High-Risk PCI) trial in 20 patients undergoing high-risk PCI with the Impella 2.5 system concluded that this device was safe, easy to implant, and hemodynamically effective (547). The Europella Registry included 144 patients undergoing high-risk PCI and reported the safety, feasibility, and potential usefulness of the device and that RCTs were warranted (548). The randomized PROTECT II (A Prospective, Multicenter, Randomized Controlled Trial of the IMPELLA Recover LP 2.5 System Versus Intra Aortic Balloon Pump in Patients Undergoing Non Emergent High Risk PCI) trial, which was designed to demonstrate superiority of Impella over IABP in terms of 1-month adverse events, was halted for futility after interim analysis of study results (549).

The TandemHeart (CardiacAssist, Inc, Pittsburgh, PA) is a left atrial to aorta catheter-based system that includes a centrifugal blood pump providing flows of up to 4 L/min. This device uses a 21 Fr cannula percutaneously inserted into the femoral vein for transseptal access of the left atrium with a 15 Fr catheter placed in the contralateral femoral artery and positioned above the aortic bifurcation. An extracorporeal pump then returns oxygenated blood from the left atrium to the arterial system, thereby unloading the left ventricle (550,551). The hemodynamic effects have been studied in patients undergoing high-risk PCI (552). Several small studies have addressed the clinical efficacy of the TandemHeart in high-risk patients undergoing PCI (551,553–556). In a single-center report of 68 patients undergoing high-risk PCI using either TandemHeart or Impella Recover 2.5, success rates (>90%) and vascular complications (7%) were similar (553).

High-risk patients may include those undergoing unprotected left main or last-remaining-conduit PCI, those with severely depressed EF undergoing PCI of a vessel supplying a large territory, and/or those with cardiogenic shock. Patient risk, hemodynamic support, ease of application/removal, and operator and laboratory expertise are all factors involved in consideration of use of these devices. With devices that require large cannula insertion, the risk of vascular injury and related complications are important considerations regarding necessity and choice of device.

5.7. Interventional Pharmacotherapy

5.7.1. Procedural Sedation

The term *conscious sedation* is falling out of favor with the recognition that there is a spectrum of procedural sedation levels. Most patients undergoing PCI fall under the definition of either minimal sedation (anxiolysis) or moderate sedation (depressed consciousness with the ability to respond purposefully to verbal commands) (557). Nonetheless, an underlying principle of procedural sedation is that the physician should be prepared to manage one level of sedation deeper than the level intended. Thus, cardiologists should be cognizant of the principles of managing deep sedation (depressed consciousness without easy arousal that may require assistance in maintaining airway patency or spontaneous ventilation).

A full review of procedural sedation is beyond the scope of this document, but practice guidelines for sedation and analgesia by nonanesthesiologists, along with The Joint Commission standards, provides a reasonable framework. These guidelines outline several general principles (558,559). Before the procedure the patient should be assessed for predictors of difficult intubation or a history of prior difficult intubation. The patient should be monitored by someone dedicated to observing the level and effects of sedation. Level of consciousness, respiratory rate, blood pressure, cardiac rhythm, and oxygen saturation by pulse oximetry should be monitored. Available equipment should include a high-flow oxygen source, suction, airway management equipment, a defibrillator, resuscitation drugs, and reversal agents appropriate for the drugs being used. A free-flowing IV line should be established. Supplemental oxygen is usually administered, even in the absence of preexisting hypoxia, to provide a margin of safety.

Agents used for sedation are best given in incremental doses, allowing adequate time for the development and assessment of peak effect. The most commonly used agents are listed in Appendix 4F.

5.7.2. Oral Antiplatelet Therapy: Recommendations

CLASS I

1. Patients already taking daily aspirin therapy should take 81 mg to 325 mg before PCI (301–304). *(Level of Evidence: B)*
2. Patients not on aspirin therapy should be given nonenteric aspirin 325 mg before PCI (301,303,304). *(Level of Evidence: B)*
3. After PCI, use of aspirin should be continued indefinitely (560–563). *(Level of Evidence: A)*
4. A loading dose of a $P2Y_{12}$ receptor inhibitor should be given to patients undergoing PCI with stenting (564–568) *(Level of Evidence: A)*. Options include

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

a. Clopidogrel 600 mg (ACS and non-ACS patients) (564–566) *(Level of Evidence: B)*
b. Prasugrel 60 mg (ACS patients) (567) *(Level of Evidence: B)*
c. Ticagrelor 180 mg (ACS patients) (568) *(Level of Evidence: B)*

5. The loading dose of clopidogrel for patients undergoing PCI after fibrinolytic therapy should be 300 mg within 24 hours and 600 mg more than 24 hours after receiving fibrinolytic therapy (565,569). *(Level of Evidence: C)*
6. Patients should be counseled on the need for and risks of DAPT before placement of intracoronary stents, especially DES, and alternative therapies should be pursued if patients are unwilling or unable to comply with the recommended duration of DAPT (208). *(Level of Evidence: C)*
7. The duration of $P2Y_{12}$ inhibitor therapy after stent implantation should generally be as follows:
   a. In patients receiving a stent (BMS or DES) during PCI for ACS, $P2Y_{12}$ inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily (570), prasugrel 10 mg daily (567), and ticagrelor 90 mg twice daily (568). *(Level of Evidence: B)*
   b. In patients receiving DES for a non-ACS indication, clopidogrel 75 mg daily should be given for at least 12 months if patients are not at high risk of bleeding (208,212,571). *(Level of Evidence: B)*
   c. In patients receiving BMS for a non-ACS indication, clopidogrel should be given for a minimum of 1 month and ideally up to 12 months (unless the patient is at increased risk of bleeding; then it should be given for a minimum of 2 weeks) (208,572). *(Level of Evidence: B)*

CLASS IIa

1. After PCI, it is reasonable to use aspirin 81 mg per day in preference to higher maintenance doses (302,573–576). *(Level of Evidence: B)*
2. If the risk of morbidity from bleeding outweighs the anticipated benefit afforded by a recommended duration of $P2Y_{12}$ inhibitor therapy after stent implantation, earlier discontinuation (e.g., <12 months) of $P2Y_{12}$ inhibitor therapy is reasonable. *(Level of Evidence: C)*

CLASS IIb

1. Continuation of DAPT beyond 12 months may be considered in patients undergoing DES implantation (567,568). *(Level of Evidence: C)*

CLASS III: HARM

1. Prasugrel should not be administered to patients with a prior history of stroke or transient ischemic attack (567). *(Level of Evidence: B)*

Aspirin reduces the frequency of ischemic complications after PCI. Although the minimum effective aspirin dosage in the setting of PCI has not been established, aspirin 325 mg given at least 2 hours, and preferably 24 hours, before PCI is recommended (302,303), after which aspirin 81 mg daily should be continued indefinitely.

Several investigations have explored various loading doses of clopidogrel before or during PCI. Compared with a 300-mg loading dose, doses of either 600 mg or 900 mg achieve greater degrees of platelet inhibition with fewer low responders (577). A meta-analysis of 7 studies that included 25,383 patients undergoing PCI demonstrated that intensified loading of clopidogrel with 600 mg reduces the rate of MACE without an increase in major bleeding compared with 300 mg (578). Another study suggested that a 600-mg loading dose of clopidogrel is associated with improvements in procedural angiographic endpoints and 1-year clinical outcomes in patients with STEMI who undergo primary PCI compared with a 300-mg dose (579). There is no benefit with increasing the loading dose to 900 mg compared with 600 mg (577). Clopidogrel 75 mg daily should be given for a minimum of 4 weeks after balloon angioplasty or BMS implantation (a minimum of 2 weeks if increased bleeding risk is present) (580) and for at least 12 months after DES implantation (unless the risk of bleeding outweighs the anticipated benefit). Patients should be counseled on the need for and risks of DAPT before stent implantation, especially DES implantation, and alternative therapies pursued (BMS or balloon angioplasty) if they are unwilling or unable to comply with the recommended duration of DAPT.

The efficacy of clopidogrel pretreatment remains controversial. Although some studies have suggested that pretreatment with clopidogrel is associated with decreased platelet aggregation and a significantly lower incidence of periprocedural MI after elective PCI, others have suggested no benefit to pretreatment compared with administration of the drug in the catheterization laboratory (572,581,582).

When prasugrel was compared with clopidogrel in patients with ACS in TRITON–TIMI 38 (Trial to Assess Improvement in Therapeutic Outcomes by Optimizing Platelet Inhibition with Prasugrel–Thrombolysis In Myocardial Infarction), prasugrel was associated with a significant 2.2% reduction in absolute risk and a 19% reduction in relative risk in the composite endpoint of cardiovascular death, nonfatal MI, or nonfatal stroke, and a significant increase in the rate of TIMI major hemorrhage (1.8% versus 2.4%) (567). Prasugrel is contraindicated in patients with a history of transient ischemic attack or stroke. Patients weighing <60 kg have an increased risk of bleeding on the 10 mg daily maintenance dose. The package insert suggests that consideration should be given to lowering the maintenance dose to 5 mg daily, although the effectiveness and safety of the 5-mg dose has not been studied. Prasugrel is not recommended for patients >75 years of age because of the increased risk of fatal and intracranial bleeding and lack of benefit, except in patients with diabetes or a history of prior MI. Prasugrel should not be started in patients likely to undergo urgent CABG. Prasugrel has not been studied in elective PCI, and thus no recommendation can be made regarding its use in this clinical setting.

Ticagrelor reversibly binds the $P2Y_{12}$ receptor. Unlike clopidogrel or prasugrel, ticagrelor is not a thienopyridine. It also does not require metabolic conversion to an active metabolite. Compared with clopidogrel in patients with ACS in the PLATO (Platelet Inhibition and Patient Outcomes) trial, ticagrelor was associated with a significant 1.9% reduction in absolute risk and a 16% reduction in relative risk in the primary composite endpoint of vascular death, nonfatal MI, or nonfatal stroke (568). Importantly, a

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

significant reduction in vascular mortality and all-cause mortality was observed. Although CABG-related bleeding was not significantly increased with ticagrelor compared with clopidogrel, a significantly greater incidence of major bleeding was observed in patients not undergoing CABG. Ticagrelor was associated with higher rates of transient dyspnea and bradycardia compared with clopidogrel, although only a very small percentage of patients discontinued the study drug because of dyspnea. Based on post hoc analysis of the PLATO study, specifically the results in the U.S. patient cohort, a black box warning states that maintenance doses of aspirin above 100 mg reduce the effectiveness of ticagrelor and should be avoided. After any initial dose, ticagrelor should be used with aspirin 75 mg to 100 mg per day (583). Given the twice-daily dosing and reversible nature of the drug, patient compliance may be a particularly important issue to consider and emphasize. Ticagrelor has not been studied in elective PCI or in patients who received fibrinolytic therapy; thus, no recommendations about its use in these clinical settings can be made.

5.7.3. IV Antiplatelet Therapy: Recommendations

STEMI

CLASS IIa

1. In patients undergoing primary PCI treated with UFH, it is reasonable to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-bolus dose tirofiban), whether or not patients were pretreated with clopidogrel (584–590). *(For GP IIb/IIIa inhibitor administration in patients not pretreated with clopidogrel, Level of Evidence: A; for GP IIb/IIIa inhibitor administration in patients pretreated with clopidogrel, Level of Evidence: C)*

CLASS IIb

1. In patients undergoing primary PCI with abciximab, it may be reasonable to administer intracoronary abciximab (589,591–604). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. Routine precatheterization laboratory (e.g., ambulance or emergency department) administration of GP IIb/IIIa inhibitors as part of an upstream strategy for patients with STEMI undergoing PCI is not beneficial (605–612). *(Level of Evidence: B)*

UA/NSTEMI

CLASS I

1. In UA/NSTEMI patients with high-risk features (e.g., elevated troponin level) not treated with bivalirudin and not adequately pretreated with clopidogrel, it is useful at the time of PCI to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-bolus dose tirofiban) in patients treated with UFH (613–618). *(Level of Evidence: A)*

CLASS IIa

1. In UA/NSTEMI patients with high-risk features (e.g., elevated troponin level) treated with UFH and adequately pretreated with clopidogrel, it is reasonable at the time of PCI to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-bolus dose tirofiban) (616,619). *(Level of Evidence: B)*

SIHD

CLASS IIa

1. In patients undergoing elective PCI treated with UFH and not pretreated with clopidogrel, it is reasonable to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-bolus dose tirofiban) (619–621). *(Level of Evidence: B)*

CLASS IIb

1. In patients undergoing elective PCI with stent implantation treated with UFH and adequately pretreated with clopidogrel, it might be reasonable to administer a GP IIb/IIIa inhibitor (abciximab, double-bolus eptifibatide, or high-bolus dose tirofiban) (619,622–624). *(Level of Evidence: B)*

See Online Data Supplement 24 for additional data regarding IV antiplatelet therapy.

In the era before DAPT, trials of adequately dosed GP IIb/IIIa inhibitors in patients undergoing balloon angioplasty and coronary stent implantation demonstrated a reduction in the incidence of composite ischemic events with GP IIb/IIIa treatment, primarily through a reduction of enzymatically defined MI (613,615,618,620,621). Earlier RCTs of GP IIb/IIIa inhibitors were generally conducted in patients treated with UFH. In some trials, use of GP IIb/IIIa inhibitors are associated with some increased bleeding risk, and trials of these agents have generally excluded patients at high risk of bleeding (e.g., coagulopathy) (584,587–589,613–618,620–626). Thus, recommendations about use of GP IIb/IIIa inhibitors are best construed as applying to those patients not at high risk of bleeding complications. Abciximab, double-bolus eptifibatide (180 mcg/kg bolus followed 10 minutes later by a second 180 mcg/kg bolus), and high-bolus dose tirofiban (25 mcg/kg) all result in a high degree of platelet inhibition (627–629), have been demonstrated to reduce ischemic complications in patients undergoing PCI (608,609,613,615,618–621), and appear to lead to comparable angiographic and clinical outcomes (630,631).

Trials of GP IIb/IIIa inhibitors in the setting of STEMI and primary PCI were conducted in the era before routine stenting and DAPT. The results of these and more recent trials, as well as several meta-analyses, have yielded mixed results (584–590). Therefore, it is reasonable to administer GP IIb/IIIa inhibitors in patients with STEMI undergoing PCI, although these agents cannot be definitively recommended as routine therapy. These agents might provide more benefit in selective use, such as in patients with large anterior MI and/or large thrombus burden. Trials of precatheterization laboratory (e.g., ambulance or emergency room) administered GP IIb/IIIa inhibitors in patients with STEMI undergoing PCI, with or without fibrinolytic therapy, have generally shown no clinical benefit, and GP IIb/IIIa inhibitor use in this setting may be associated with an increased risk of bleeding (605–610,612). Studies of intracoronary GP IIb/IIIa inhibitor administration (predominantly using abciximab) consist of several small RCTs, retrospective analyses, retrospective and prospective regis-

Table 12. Dosing of Parenteral Anticoagulants During PCI

Drug	Patient Has Received Prior Anticoagulant Therapy	Patient Has Not Received Prior Anticoagulant Therapy
UFH	• IV GPI planned: additional UFH as needed (e.g., 2,000 to 5,000 U) to achieve an ACT of 200 to 250 s • No IV GPI planned: additional UFH as needed (e.g., 2,000 to 5,000 U) to achieve an ACT of 250 to 300 s for HemoTec, 300 to 350 s for Hemochron	• IV GPI planned: 50 to 70 U/kg bolus to achieve an ACT of 200 to 250 s • No IV GPI planned: 70 to 100 U/kg bolus to achieve target ACT of 250 to 300 s for HemoTec, 300 to 350 s for Hemochron
Enoxaparin	• For prior treatment with enoxaparin, if the last SC dose was administered 8 to 12 h earlier or if only 1 SC dose of enoxaparin has been administered, an IV dose of 0.3 mg/kg of enoxaparin should be given. • If the last SC dose was administered within the prior 8 h, no additional enoxaparin should be given.	0.5 to 0.75 mg/kg IV bolus
Bivalirudin	For patients who have received UFH, wait 30 min, then give 0.75 mg/kg IV bolus, then 1.75 mg/kg per h IV infusion.	0.75 mg/kg bolus, 1.75 mg/kg per h IV infusion
Fondaparinux	For prior treatment with fondaparinux, administer additional IV treatment with an anticoagulant possessing anti-IIa activity, taking into account whether GPI receptor antagonists have been administered.	N/A
Argatroban	200 mcg/kg IV bolus, then 15 mcg/kg per min IV infusion	350 mcg/kg bolus, then 15 mcg/kg per min IV infusion

ACT indicates activated clotting time; IV, intravenous; GPI, glycoprotein inhibitor; N/A, not applicable; PCI, percutaneous coronary intervention; SC, subcutaneous; and UFH, unfractionated heparin.

tries, cohort analyses, and case reports. Although most of these published studies have reported some benefit of intracoronary administration in terms of acute angiographic parameters, infarct size, left ventricle myocardial salvage, and composite clinical endpoints, several other studies have not detected any benefit with intracoronary administration (589,591–604).

Trials of GP IIb/IIIa inhibitors in patients with UA/NSTEMI undergoing PCI demonstrated reduced ischemic outcomes, particularly in those with high-risk features such as positive biomarkers. Most trials were conducted in a prior PCI era and without $P2Y_{12}$ inhibitor pretreatment (613,615,618,632,633), although several trials have also demonstrated benefit in patients with high-risk features pretreated with clopidogrel (616,619). In most older studies of stable patients undergoing balloon angioplasty or coronary stenting, treatment with GP IIb/IIIa inhibitors resulted in a reduction of composite ischemic events, primarily enzymatically defined MI (613–618,620,621,634,635). More contemporary trials of patients pretreated with a thienopyridine have not demonstrated any benefit with GP IIb/IIIa inhibitor therapy in patients with stable symptoms undergoing elective PCI (619,622–624).

5.7.4. Anticoagulant Therapy

5.7.4.1. USE OF PARENTERAL ANTICOAGULANTS DURING PCI: RECOMMENDATION

CLASS I

1. An anticoagulant should be administered to patients undergoing PCI. *(Level of Evidence: C)*

Anticoagulant therapy prevents thrombus formation at the site of arterial injury, on the coronary guidewire, and in the catheters used for PCI (8). With rare exceptions (636), all PCI studies have used some form of anticoagulant. It is the consensus of the writing committee that PCI be performed with the use of some form of anticoagulant therapy. Suggested dosing regimens of parenteral agents used in PCI are given in Table 12. Recommendations for antiplatelet and antithrombin pharmacotherapy in PCI are given in Table 13.

5.7.4.2. UFH: RECOMMENDATION

CLASS I

1. Administration of IV UFH is useful in patients undergoing PCI. *(Level of Evidence: C)*

As the only anticoagulant available for PCI for many years, UFH became the standard of care by default (8). The dose of UFH for PCI has been based on empiricism and experience from RCTs. Suggested UFH dosing regimens are given in Table 12. When UFH is used during PCI, most cardiologists assess the degree of anticoagulation by measuring the activated clotting time. Although measurements are useful to show that an anti-IIa anticoagulant has been given, the value of the activated clotting time in current practice has been questioned. Although studies in the balloon angioplasty era did demonstrate a relationship between activated clotting time levels and ischemic complications (653–655), more recent analyses from the coronary stent era have not found a clear relationship between activated clotting time and outcomes (349,656,657). There may, however, be a modest relation between bleeding and activated clotting time levels (349,657). In addition, not only are there differences between activated clotting time levels measured by Hemochron and HemoTec devices, but both devices have less than optimal precision (658). Thus, although traditional target activated clotting time levels are included in this document, the utility of measured activated clotting time levels in current practice should be considered uncertain.

Table 13. Recommendations for Antiplatelet and Antithrombin Pharmacotherapy at the Time of PCI

	COR	LOE	References	Relevant Caveats/Comments
Oral antiplatelet agents				
Aspirin	I	B	(301–304, 560–563)	N/A
$P2Y_{12}$ inhibitors	I	A	(564–568)	• A loading dose of a $P2Y_{12}$ inhibitor should be given to patients undergoing PCI with stenting.
• Clopidogrel	I	B	(564–566)	• 600-mg loading dose now recommended.
• Prasugrel	I	B	(567)	• Contraindicated in patients with prior TIA/CVA: ***Class III: Harm; LOE: B.*** • Generally not recommended in patients >75 y of age (Section 5.7.2). • Consideration of using a lower maintenance dose in patients weighing <60 kg suggested by FDA (Section 5.7.2).
• Ticagrelor	I	B	(568)	• Issues of patient compliance may be especially important.
GP IIb/IIIa inhibitors (abciximab, double-bolus eptifibatide, high-bolus dose tirofiban)				
• No clopidogrel pretreatment	STEMI: IIa	A	(584–590)	• UA/NSTEMI recommendation applies to those with high-risk features. • GPI use in STEMI may be most appropriate in those with large anterior MI and/or large thrombus burden. • IC abciximab administration in STEMI: ***Class IIb; LOE: B.*** • Precatheterization laboratory GPI administration in STEMI: ***Class III: No Benefit; LOE: B.*** • Recommendations apply to those not at high risk for bleeding complications.
	UA/NSTEMI: I	A	(613–618)	
	SIHD: IIa	B	(619–621)	
• Clopidogrel pretreatment	STEMI: IIa	C	(584–590)	
	UA/NSTEMI: IIa	B	(616, 619)	
	SIHD: IIb	B	(619, 622–624)	
Antithrombin agents				
UFH	I	C	N/A	• Dosing based on whether or not GPI was administered.
Bivalirudin	I	B	(625, 637–645)	• Lower bleeding rates associated with bivalirudin are mitigated when used concomitantly with a GPI.
Enoxaparin	IIb	B	(646–650)	• Recommendations apply to administration of IV enoxaparin at the time of PCI for those who have not received prior antithrombin therapy or who have received "upstream" SC enoxaparin therapy for UA/NSTEMI. • An additional dose of 0.3 mg/kg IV enoxaparin should be administered at the time of PCI to patients who have received <2 therapeutic SC doses (e.g., 1 mg/kg) or received the last SC enoxaparin dose 8 to 12 h before PCI: ***Class I; LOE: B.*** • Patients treated with SC enoxaparin within 12 h of PCI should not receive additional treatment with UFH during PCI ("stacking"): ***Class III: Harm; LOE: B.***
Anti-Xa inhibitors				
Fondaparinux	III: Harm	C	(651, 652)	• PCI should not be performed with fondaparinux as the sole antithrombin agent in patients treated with upstream fondaparinux. An additional anticoagulant with anti-IIa activity should be administered.

ACT indicates activated clotting time; COR, class of recommendation; CVA, cerebrovascular accident; FDA, U.S. Food and Drug Administration; GP, glycoprotein; GPI, glycoprotein IIb/IIIa inhibitor; IC, intracoronary; IV, intravenous; LOE, level of evidence; MI, myocardial infarction; N/A, not applicable; PCI, percutaneous coronary intervention; SC, subcutaneous; SIHD, stable ischemic heart disease; STEMI, ST-elevation myocardial infarction; TIA, transient ischemic attack; UA/NSTEMI, unstable angina/non–ST-elevation myocardial infarction; and UFH, unfractionated heparin.

Most cardiologists remove femoral sheaths when the activated clotting time falls to <150 to 180 seconds or when the activated partial thromboplastin time falls to <50 seconds. Full-dose anticoagulation is no longer used after successful PCI procedures. Almost all large clinical trials have enrolled patients who underwent transfemoral PCI, but recent small studies assessing the transradial approach have used similar doses of UFH (659) and similar activated clotting time target levels (660).

5.7.4.3. ENOXAPARIN: RECOMMENDATIONS

CLASS I

1. An additional dose of 0.3 mg/kg IV enoxaparin should be administered at the time of PCI to patients who have received fewer than 2 therapeutic subcutaneous doses (e.g., 1 mg/kg) or received the last subcutaneous enoxaparin dose 8 to 12 hours before PCI (649,661–664). *(Level of Evidence: B)*

CLASS IIb

1. Performance of PCI with enoxaparin may be reasonable in patients either treated with "upstream" subcutaneous enoxaparin for UA/NSTEMI or who have not received prior antithrombin therapy and are administered IV enoxaparin at the time of PCI (646–650). (*Level of Evidence: B*)

CLASS III: HARM

1. UFH should not be given to patients already receiving therapeutic subcutaneous enoxaparin (649,665). *(Level of Evidence: B)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

Trials of enoxaparin relevant to PCI include both studies in which patients with UA/NSTEMI were started on upstream subcutaneous enoxaparin therapy that was continued up to the time of PCI and trials in which patients who had received no prior antithrombin therapy were treated with IV enoxaparin at the time of PCI (646–650,661–663,666). In the SYNERGY (Superior Yield of the New strategy of Enoxaparin, Revascularization and Glycoprotein IIb/IIIa Inhibitors) trial, there was an increased incidence of bleeding in those treated with upstream enoxaparin, later attributed at least in part to the fact that some patients being treated with enoxaparin were also administered UFH at the time of PCI (so-called "stacking") (649,665). Almost all patients undergoing elective PCI who are administered enoxaparin (0.5 mg/kg IV) will have a peak anti-Xa level >0.5 IU/mL (647). Most clinical studies have used a regimen of 0.5 to 0.75 mg IV (667). Several studies have used this regimen in elective patients and those with STEMI (646). Patients who have received multiple doses of subcutaneously administered enoxaparin who undergo PCI within 8 hours of the last subcutaneous dose generally have adequate degrees of anticoagulation to undergo PCI, but the degree of anticoagulation may diminish in the 8- to 12-hour period after the last subcutaneous dose. In such patients, as well as in patients who have received only 1 subcutaneous dose of enoxaparin, the addition of enoxaparin (0.3 mg/kg IV) at the time of PCI provides an additional degree of anticoagulation and has become standard practice (648,661–664). Patients who undergo PCI >12 hours after the last subcutaneous dose are usually treated with full-dose de novo anticoagulation using an established regimen (e.g., full-dose UFH or bivalirudin).

5.7.4.4. BIVALIRUDIN AND ARGATROBAN: RECOMMENDATIONS

CLASS I

1. For patients undergoing PCI, bivalirudin is useful as an anticoagulant with or without prior treatment with UFH (625,637–645). *(Level of Evidence: B)*
2. For patients with heparin-induced thrombocytopenia, it is recommended that bivalirudin or argatroban be used to replace UFH (668,669). *(Level of Evidence: B)*

Bivalirudin is being increasingly used in clinical practice (670) as evidence emerges from clinical trials across the spectrum of CAD (638–644). In individual trials and meta-analyses, the use of bivalirudin has been associated with reduced bleeding compared with UFH plus a GP IIb/IIIa inhibitor, although concerns about ischemic events have emerged in individual studies (625,637–645). Longer-term follow-up of the major bivalirudin trials, however, suggests that small or nominal increases in ischemic events have not translated into long-term consequences and that treatment at or before the time of PCI with clopidogrel may mitigate any increased early ischemic risk (637–645). Thus, a treatment strategy of bivalirudin compared with heparin (or enoxaparin) plus GP IIb/IIIa inhibitor appears to lower the risk of bleeding complications. The lower bleeding rates associated with bivalirudin (compared with UFH plus a GP IIb/IIIa inhibitor) are mitigated when used concomitantly with a GP IIb/IIIa inhibitor (639). A strategy of use of provisional GP IIb/IIIa inhibitor in patients treated with bivalirudin is widely accepted (639,643,644).

In patients with heparin-induced thrombocytopenia (671,672), a direct-thrombin inhibitor (argatroban) has been approved as an alternative parenteral anticoagulant to be used during PCI (668). The use of bivalirudin for heparin-induced thrombocytopenia has been reported as well (669).

5.7.4.5. FONDAPARINUX: RECOMMENDATION

CLASS III: HARM

1. Fondaparinux should not be used as the sole anticoagulant to support PCI. An additional anticoagulant with anti-IIa activity should be administered because of the risk of catheter thrombosis (651,652). *(Level of Evidence: C)*

Fondaparinux, a pentasaccharide, is an indirect factor Xa inhibitor but has no effect on thrombin. On the basis of reports of catheter thrombosis when fondaparinux is used alone during primary PCI (651,652), the writing committee recommends that an anticoagulant with anti-IIa activity be used in patients undergoing PCI (651,652). One study suggested that clinical outcomes were better when fondaparinux was replaced during PCI by a standard dose of UFH (85 U/kg, 60 U/kg with GP IIb/IIIa inhibitors) rather than by a low dose (50 U/kg) (673).

5.7.5. No-Reflow Pharmacological Therapies: Recommendation

CLASS IIa

1. Administration of an intracoronary vasodilator (adenosine, calcium channel blocker, or nitroprusside) is reasonable to treat PCI-related no-reflow that occurs during primary or elective PCI (674–689). *(Level of Evidence: B)*

See Online Data Supplement 25 for additional data regarding no-reflow therapies.

No-reflow is a broad term used to describe 2 distinct entities. The first is "interventional no-reflow" attributed to vasospasm and downstream embolization of debris dislodged during PCI, usually in the setting of atherectomy, thrombus, or degenerated SVGs. The second entity is suboptimal reperfusion of an infarct artery, attributed to endothelial injury in addition to embolization and vasospasm. Angiographic no-reflow is the most obvious sequela of the same pathophysiology that produces abnormal TIMI frame counts and TIMI blush scores, so these measures are often used interchangeably. The principal clinical sequela of no-reflow is myonecrosis. Efforts to prevent no-reflow overlap with strategies to reduce MI size and prevent periprocedural MI.

In the setting of MI, several drugs have been shown to reduce the incidence of no-reflow. Evidence for a beneficial effect on no-reflow exists for abciximab, adenosine, nic-

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

orandil, and nitroprusside (674,675,680,682,683,685,687,688,690). However, their adoption into clinical practice has depended on their effect on hard clinical endpoints such as infarct size and mortality. These benefits, and consequentially the use of these agents, have been limited.

For interventional no-reflow, several therapies have proven effective after no-reflow has started. These include adenosine, calcium channel blockers, and nitroprusside (676,678,679,681,684,686,689,691). There are fewer data to support the use of epinephrine (692). No-reflow after rotational atherectomy was less common with nicorandil compared with verapamil infusions in 3 studies (693–695), and an infusion of nicorandil/adenosine during rotational atherectomy prevented no-reflow in 98% of patients (677). Trials of pre-PCI intracoronary verapamil, nicardipine, and adenosine have reported them to be safe but have not demonstrated reductions in post-PCI no-reflow (696–698). Mechanical devices to prevent interventional and myocardial infarct reperfusion no-reflow are also covered in Section 5.5.5.

5.8. PCI in Specific Anatomic Situations

5.8.1. CTOs: Recommendation

CLASS IIa

1. PCI of a CTO in patients with appropriate clinical indications and suitable anatomy is reasonable when performed by operators with appropriate expertise (699–703). *(Level of Evidence: B)*

See Online Data Supplements 26 to 28 for additional data regarding CTOs.

Approximately one third of patients with suspected CAD who undergo coronary angiography have ≥1 CTO (defined as occlusion of a duration >3 months) (704). Although stress-induced ischemia can be elicited in the majority of patients with CTO despite the presence of collaterals (706,707), only 8% to 15% of these patients undergo PCI (708,709). The disparity between the frequency of CTOs and percutaneous treatment underscores not only the technical and procedural complexities of this lesion subtype but also the clinical uncertainties regarding which patients benefit from CTO revascularization. Studies suggest that patients who undergo successful, rather than failed, recanalization of CTOs fare better in terms of symptom status and need for CABG (699), as well as LV function (710). However, the impact of successful CTO recanalization on long-term survival remains unsettled (701,711,712). The decision to try PCI for a CTO (versus continued medical therapy or surgical revascularization) requires an individualized risk-benefit analysis encompassing clinical, angiographic, and technical considerations. Consultation with a cardiothoracic surgeon and use of the Heart Team approach in cases of CTO in which a large territory is subtended and/or multivessel CAD is present are frequently done.

From a technical perspective, successful recanalization of CTOs has steadily increased over the years because of adoption of dedicated wires, novel techniques, and increased operator experience (702). In patients who undergo successful CTO recanalization, use of DES significantly reduces the need for repeated target-vessel revascularization, compared with BMS and balloon angioplasty, without compromising safety (703,713–719).

5.8.2. SVGs: Recommendations

CLASS I

1. EPDs should be used during SVG PCI when technically feasible (532–535). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. Platelet GP IIb/IIIa inhibitors are not beneficial as adjunctive therapy during SVG PCI (212,571,720,721). *(Level of Evidence: B)*

CLASS III: HARM

1. PCI is not recommended for chronic SVG occlusions (722–724). *(Level of Evidence: C)*

See Online Data Supplement 29 for additional data regarding SVG.

Adverse cardiac event rates are doubled after SVG PCI compared with native-artery PCI (536). A distal balloon occlusion EPD decreased the 30-day composite outcome of death, MI, emergency CABG, or target-lesion revascularization (9.6% versus 16.5%) in the only RCT comparing embolic protection with no embolic protection (532). Subsequent noninferiority comparisons have demonstrated similar benefit with proximal occlusion and distal filter EPDs, with benefit limited to reduction in periprocedural MI (534,535). PCI in chronic SVG occlusion is associated with low success rates, high complication rates, and poor long-term patency rates (722,723). Restenosis and target-vessel revascularization rates are lower with DES compared with BMS, although mortality and stent thrombosis rates are similar (725). The use of covered stents is limited to the treatment of the uncommon complication of SVG perforation. Balloon angioplasty for distal SVG anastomotic stenoses has low restenosis rates (724), so stenting is commonly reserved at this location for suboptimal balloon angioplasty results or restenosis. Routine GP IIb/IIIa inhibitor therapy has not proven beneficial in SVG PCI (720). Fibrinolytic therapy is no longer used for thrombus-containing lesions, but rheolytic or manual aspiration thrombectomy is sometimes employed.

5.8.3. Bifurcation Lesions: Recommendations

CLASS I

1. Provisional side-branch stenting should be the initial approach in patients with bifurcation lesions when the side branch is not large and has only mild or moderate focal disease at the ostium (726–729). *(Level of Evidence: A)*

CLASS IIa

1. It is reasonable to use elective double stenting in patients with complex bifurcation morphology involving a large side branch where the risk of side-branch occlusion is high and the likelihood of

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

successful side-branch reaccess is low (730–733). *(Level of Evidence: B)*

Side-branch occlusion or severe stenosis after stenting the main artery in coronary bifurcation PCI occurs in 8% to 80% of unselected patients (732,734). The frequency of side-branch occlusion is related to complex bifurcation morphology (severe and/or long side-branch ostial stenosis, large plaque burden in the side-branch ostium, and/or unfavorable side-branch angulation) (732,735,736). Side-branch occlusion after PCI is associated with Q-wave and non–Q-wave MI (734,735). Therefore, preservation of physiologic flow in the side branch after PCI is important (736). There are 2 bifurcation PCI strategies: provisional stenting (stenting the main vessel with additional balloon angioplasty or stenting of the side branch only in the case of an unsatisfactory result) and elective double stenting of the main vessel and the side branch. When there is an unsatisfactory result in the side branch from the provisional stent in the main branch, sometimes balloon angioplasty alone in the side branch will improve the result and stenting the side branch is not necessary. Some experts have suggested that using the side-branch balloon alone will distort the main branch stent and thus this always needs to be a kissing balloon inflation.

In patients with low-risk bifurcation lesions (minimal or moderate ostial side-branch disease [<50% diameter stenosis] of focal length [5 to 6 mm]), provisional stenting yields similar clinical outcome to elective double stenting, with lower incidence of periprocedural biomarker elevation (726–729). Conversely, in patients with high-risk bifurcations, elective double stenting is associated with a trend toward higher angiographic success rates, lower in-hospital MACE, and better long-term patency of the side branch compared with provisional stenting (193). Culotte, Crush, and T-stent techniques have been studied in RCTs (726–729,737). Use of DES yields better outcomes than BMS (738), and sirolimus-eluting stents yield better outcomes than paclitaxel-eluting stents (739–742). Clinical evidence supports the use of final kissing balloon inflation after elective double stenting (743).

5.8.4. Aorto-Ostial Stenoses: Recommendations

CLASS IIa

1. IVUS is reasonable for the assessment of angiographically indeterminant left main CAD (744,745). *(Level of Evidence: B)*
2. Use of DES is reasonable when PCI is indicated in patients with an aorto-ostial stenosis (746,747). *(Level of Evidence: B)*

Aorto-ostial stenoses of native coronary arteries (left main coronary artery and right coronary artery) are most commonly caused by atherosclerosis, but they can also occur in patients with congenital malformations, radiation exposure, vasculitides, and aortic valve replacement. The angiographic diagnosis of aorto-ostial disease is not always straightforward, especially in the ostial left main coronary artery, where eccentricity and angulation can be mistaken for stenosis (490,748). Aorto-ostial disease can be evaluated with IVUS (744,745); FFR (with IV adenosine) has also been used (484,749). The treatment of aorto-ostial stenoses with balloon angioplasty has been associated with lower procedural success rates, more frequent in-hospital complications, and a greater likelihood of late restenosis (750). Although atherectomy devices (directional atherectomy, rotational atherectomy, and excimer laser angioplasty) have improved acute angiographic results over balloon angioplasty, restenosis has remained a limitation (751). In patients with aorto-ostial stenoses undergoing PCI, use of DES has been shown to reduce restenosis compared with BMS (176,746,752).

5.8.5. Calcified Lesions: Recommendation

CLASS IIa

1. Rotational atherectomy is reasonable for fibrotic or heavily calcified lesions that might not be crossed by a balloon catheter or adequately dilated before stent implantation (514,515,520). *(Level of Evidence: C)*

The presence of coronary calcification is a marker for significant CAD and increased long-term mortality (753). Calcified coronary lesions are not a homogenous entity, and their response to PCI varies according to severity of calcification. Severely calcified lesions respond poorly to balloon angioplasty (230,754), and when stents are implanted in such lesions, an incomplete and asymmetrical stent expansion occurs in the majority of cases (755). Attempts to remedy the underexpanded stents with aggressive high-pressure balloon dilatation may result in coronary artery rupture (756). All the published prospective RCTs that evaluated the various catheter-based coronary interventional devices excluded patients with severely calcified lesions. Therefore, the evidence base for best PCI practices in patients with severely calcified lesions comes from nonrandomized single-arm studies. Among the various adjunct devices that are used to facilitate PCI in severely calcified lesions, only rotational atherectomy has been shown to have potential utility (514,757). Although rotational atherectomy increases the chances of angiographic success in severely calcified lesions, its use as a stand-alone device has not led to a reduction in restenosis (520,521,758). Several retrospective studies have shown that in patients with severely calcified lesions, the use of rotational atherectomy before implantation of BMS (514) or DES (515) is safe. Intermediate-term patency is more favorable with DES than BMS (759).

5.9. PCI in Specific Patient Populations

Several specific patient subsets with higher risks for PCI, and at times higher absolute clinical benefit, have traditionally been underrepresented in RCTs and are described below.

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

5.9.1. Elderly

The elderly constitute a growing proportion of patients considered for PCI (760). In 1 series examining trends over a 25-year period, the proportion of patients undergoing PCI who were 75 to 84 years of age doubled, and those >85 years of age increased 5-fold (761). Age is one of the strongest predictors of mortality after PCI (762), and elderly patients present with a substantially higher clinical risk profile (760). Nonetheless, the angiographic success rates and clinical benefits of PCI in elderly patients are similar to younger patients (763). In fact, the absolute benefit is typically greater because of higher absolute risk of adverse outcomes in these patients (764). However, increased risks of complications such as major bleeding and stroke mandate careful consideration of the benefits and risks of PCI in elderly patients (373).

5.9.2. Diabetes

Patients with diabetes represent approximately one third of patients undergoing PCI in the United States. Restenosis, which had been a major limitation of PCI, is significantly reduced in patients with diabetes treated with DES compared with BMS (471). However, there are no definitive data from RCTs supporting different clinical outcomes for different types of DES (765), with a recent meta-analysis of 35 RCTs involving 3,852 patients with diabetes unable to find major differences between patients receiving sirolimus-eluting stents or paclitaxel-eluting stents (472). Numerous analyses and clinical studies have evaluated how the presence of diabetes may impact the clinical outcome of patients undergoing PCI and decisions about PCI or CABG (14,116,163,164,186). These studies and the approach to revascularization decisions in diabetes are addressed in Section 4.

Diabetes is an important risk factor for the development of contrast-induced AKI. Strategies to reduce the risk of contrast-induced AKI in patients with diabetes are discussed in Section 4.4.

5.9.3. Women

Cardiovascular disease is the leading cause of death in women in the United States and Europe (766), and an estimated 35% of PCIs in the United States are performed in women (767,768). Women undergoing PCI usually have more risk factors (including hypertension, advanced age, elevated cholesterol, and more significant and diffuse CAD) compared with men (769). Women with STEMI are also less likely to receive early medical treatments and experience longer delays to reperfusion therapy (770,771). In subgroup analyses of clinical trials, use of DES appears to be similarly efficacious in women and men (772).

5.9.4. CKD: Recommendation

CLASS I

1. In patients undergoing PCI, the glomerular filtration rate should be estimated and the dosage of renally cleared medications should be adjusted (298–300). *(Level of Evidence: B)*

CKD is an independent risk factor for the development and progression of CAD (773,774), and is also associated with worse prognosis after MI or PCI (369,775). A glomerular filtration rate of <60 mL/min per 1.73 m^2 of body surface area should be considered abnormal. Patients with CKD undergoing PCI have a higher risk of complications, including bleeding (776), AKI, and death (236,777), but CKD is not a strong predictor of restenosis after BMS or DES (778). Strategies to reduce the risk of contrast-induced AKI in patients with CKD are discussed in Section 4.4. Platelet dysfunction and overdosing of antiplatelet and antithrombin drugs (350) in patients with CKD contribute to the increased risk of bleeding. The Cockcroft-Gault formula is commonly used as a surrogate marker for estimating creatinine clearance, which in turn estimates glomerular filtration rate (298,299,779,780). Medications that require dosage adjustments in patients with CKD include eptifibatide, tirofiban, bivalirudin, enoxaparin, and fondaparinux (781).

5.9.5. Cardiac Allografts

Cardiac allograft vasculopathy is a major cause of death in cardiac transplant recipients after their first year of survival (782). In general, revascularization for cardiac allograft vasculopathy with PCI is only palliative, with no evidence supporting benefit in regard to long-term survival or avoidance of retransplantation. The restenosis rate after PCI in patients with cardiac allograft vasculopathy is high, although stent implantation reduces early and midterm restenosis compared with balloon angioplasty. DES have been shown to have a tendency to lower restenosis rates compared with BMS (783,784). Thus, many clinicians perform stenting with DES or BMS in cardiac transplant patients with discrete lesions who have an abnormal stress test or symptoms suggestive of myocardial ischemia.

5.10. Periprocedural MI Assessment: Recommendations

CLASS I

1. In patients who have signs or symptoms suggestive of MI during or after PCI or in asymptomatic patients with significant *persistent* angiographic complications (e.g., large side-branch occlusion, flow-limiting dissection, no-reflow phenomenon, or coronary thrombosis), creatinine kinase-MB and troponin I or T should be measured. *(Level of Evidence: C)*

CLASS IIb

1. Routine measurement of cardiac biomarkers (creatinine kinase-MB and/or troponin I or T) in all patients after PCI may be reasonable. *(Level of Evidence: C)*

Major events leading to ischemia or MI after PCI include acute closure, embolization and no-reflow, side-branch occlusion, and acute stent thrombosis. Issues surrounding

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

the routine assessment of cardiac biomarkers after PCI are complex, especially given that the definition of PCI-related MI has evolved over the years and most events are asymptomatic. The most recent consensus definition of MI considers troponin elevations of 3 times the upper limit of normal as a PCI-related MI in patients with normal baseline levels; this is further classified as a type 4a MI (240). This definition is supported by studies with delayed-enhancement MRI confirming that there is irreversible injury in the myocardium associated with biomarker elevations and that the size of this injury correlates with the degree of elevation (785). Furthermore, a meta-analysis of 15 observational studies found that troponin elevations at any level were linked with worse in-hospital and long-term outcomes; elevations >3 times the upper limit of normal predicted even worse outcomes (242). Other observational data, however, have raised concerns about whether the relationship is causal (786,787). A recent study found creatinine kinase-MB to correlate better with MRI-detected MI than troponin level (788). Definitions of PCI-related MI are being reevaluated by the Task Force for the Redefinition of Myocardial Infarction. Although there may be value for individual operators and hospitals to routinely measure cardiac biomarkers to track rates of PCI-related MI, at present there are not compelling data to recommend this for all PCI procedures.

5.11. Vascular Closure Devices: Recommendations

CLASS I

1. Patients considered for vascular closure devices should undergo a femoral angiogram to ensure their anatomic suitability for deployment. *(Level of Evidence: C)*

CLASS IIa

1. The use of vascular closure devices is reasonable for the purposes of achieving faster hemostasis and earlier ambulation compared with the use of manual compression (257,789–791). *(Level of Evidence: B)*

CLASS III: NO BENEFIT

1. The routine use of vascular closure devices is not recommended for the purpose of decreasing vascular complications, including bleeding (256,257,789–792). *(Level of Evidence: B)*

See Online Data Supplement 30 for additional data regarding vascular closure devices.

Vascular (arteriotomy) closure devices have been extensively reviewed (790), most recently in a 2010 AHA scientific statement (257), which issued several formal recommendations. The results of 4 meta-analyses have found that vascular closure devices decrease time to hemostasis compared with manual compression but do not decrease vascular complications, bleeding complications, or the need for blood transfusions (256,789,791,793). Future studies of vascular closure devices need to be randomized, include "high-risk" patients and "high-risk" anatomy, use blinded endpoint adjudication as much as possible, use well-defined and comprehensive complication endpoints, and be adequately powered to detect clinically important endpoints, particularly bleeding and vascular complications.

6. Postprocedural Considerations

Postprocedural considerations in patients undergoing PCI are discussed below and summarized in Table 14. Some recommendations and text regarding DAPT in Section 5.7.2 are intentionally repeated in this section for reader ease of use.

6.1. Postprocedural Antiplatelet Therapy: Recommendations

CLASS I

1. After PCI, use of aspirin should be continued indefinitely (560–563). *(Level of Evidence: A)*
2. The duration of $P2Y_{12}$ inhibitor therapy after stent implantation should generally be as follows:
   a. In patients receiving a stent (BMS or DES) during PCI for ACS, $P2Y_{12}$ inhibitor therapy should be given for at least 12 months. Options include clopidogrel 75 mg daily (570), prasugrel 10 mg daily (567), and ticagrelor 90 mg twice daily (568). *(Level of Evidence: B)*
   b. In patients receiving DES for a non-ACS indication, clopidogrel 75 mg daily should be given for at least 12 months if the patient is not at high risk of bleeding (208,212,571). *(Level of Evidence: B)*
   c. In patients receiving BMS for a non-ACS indication, clopidogrel should be given for a minimum of 1 month and ideally up to 12 months (unless the patient is at increased risk of bleeding; then it should be given for a minimum of 2 weeks) (572). *(Level of Evidence: B)*
3. Patients should be counseled on the importance of compliance with DAPT and that therapy should not be discontinued before discussion with their cardiologist (208). *(Level of Evidence: C)*

CLASS IIa

1. After PCI, it is reasonable to use aspirin 81 mg per day in preference to higher maintenance doses (302,573–576). *(Level of Evidence: B)*
2. If the risk of morbidity from bleeding outweighs the anticipated benefit afforded by a recommended duration of $P2Y_{12}$ inhibitor therapy after stent implantation, earlier discontinuation (e.g., <12 months) of $P2Y_{12}$ inhibitor therapy is reasonable. *(Level of Evidence: C)*

CLASS IIb

1. Continuation of clopidogrel, prasugrel, or ticagrelor beyond 12 months may be considered in patients undergoing placement of DES (567,568). *(Level of Evidence: C)*

Continued treatment with the combination of aspirin and a $P2Y_{12}$ inhibitor antagonist after PCI appears to reduce MACE (570,572). On the basis of RCT protocols, secondary prevention measures, and expert consensus opinion, aspirin 81 mg daily should be given indefinitely after PCI.

Likewise, $P2Y_{12}$ inhibitors should be given for a minimum of 1 month after BMS (minimum 2 weeks for patients at significant increased risk of bleeding) (580) and for 12 months after DES and ideally in all patients who are not at high risk of bleeding.

The 2009 STEMI/PCI guidelines update (10) listed the recommendation "if the risk of morbidity because of bleed-

ing outweighs the anticipated benefit afforded by thienopyridine therapy, earlier discontinuation *should be considered*" as a Class I recommendation, although the language used, in part, was consistent with a Class IIa recommendation. To clarify the intent of the recommendation, as well as to acknowledge the inherent difficulties in weighing bleeding and stent thrombosis risks, the recommendation is designated a Class IIa recommendation, using the phrase "earlier discontinuation *is reasonable*." Recommendations regarding $P2Y_{12}$ inhibitor discontinuation before elective or urgent CABG are provided in the "2011 ACCF/AHA Guideline for Coronary Artery Bypass Graft Surgery" (824).

6.1.1. PPIs and Antiplatelet Therapy: Recommendations

CLASS I

1. PPIs should be used in patients with a history of prior gastrointestinal (GI) bleeding who require DAPT (794). *(Level of Evidence: C)*

CLASS IIa

1. Use of PPIs is reasonable in patients with an increased risk of GI bleeding (e.g., advanced age, concomitant use of warfarin, steroids, nonsteroidal anti-inflammatory drugs, *Helicobacter pylori* infection) who require DAPT (794). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. Routine use of a PPI is not recommended for patients at low risk of GI bleeding, who have much less potential to benefit from prophylactic therapy (794). *(Level of Evidence: C)*

See Online Data Supplement 31 for additional data regarding the clopidogrel–PPI interaction.

PPIs are often prescribed prophylactically when clopidogrel is started to prevent GI complications such as ulceration and bleeding due to DAPT (825). There is pharmacodynamic evidence that omeprazole interferes with clopidogrel metabolism (826,827), but there is no clear evidence implicating other PPIs. However, even with omeprazole, there are no convincing data supporting an important clinical drug–drug interaction (826). The FDA communication about an ongoing safety review of clopidogrel advises that healthcare providers avoid the use of clopidogrel in patients with impaired *CYP2C19* function due to known genetic variation or drugs that inhibit *CYP2C19* activity. The FDA notes that there is no evidence that other drugs that reduce stomach acid, such as histamine-2 receptor antagonists (except cimetidine) or antacids, interfere with clopidogrel responsiveness. The COGENT (Clopidogrel and the Optimization of Gastrointestinal Events) trial randomized patients with DAPT to clopidogrel and omeprazole or clopidogrel and placebo, and while there was no difference in cardiovascular events between the 2 groups, GI events were halved in those randomized to omeprazole (828). It is reasonable to carefully evaluate the indication for PPI therapy in patients treated with clopidogrel, based on the presence or absence of the risk factors discussed above (794). The need for GI protection increases with the number of risk factors for bleeding. Prior upper GI bleeding is the strongest and most consistent risk factor for GI bleeding on antiplatelet therapy. Patients with ACS and prior upper GI bleeding are at substantial cardiovascular risk, so DAPT with concomitant use of a PPI may provide the optimal balance of risk and benefit. It should be noted that PPIs, by decreasing adverse GI effects related to clopidogrel, might decrease patients' discontinuation of clopidogrel. In patients in whom there is a clear indication for PPI therapy, some clinicians may choose to use a PPI other than omeprazole.

6.1.2. Clopidogrel Genetic Testing: Recommendations

CLASS IIb

1. Genetic testing might be considered to identify whether a patient at high risk for poor clinical outcomes is predisposed to inadequate platelet inhibition with clopidogrel (829). *(Level of Evidence: C)*
2. When a patient predisposed to inadequate platelet inhibition with clopidogrel is identified by genetic testing, treatment with an alternate $P2Y_{12}$ inhibitor (e.g., prasugrel or ticagrelor) might be considered (829). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. The routine clinical use of genetic testing to screen patients treated with clopidogrel who are undergoing PCI is not recommended (829). *(Level of Evidence: C)*

On March 12, 2010, the FDA approved a new label for clopidogrel with a "boxed warning" about the diminished effectiveness of clopidogrel in patients with impaired ability to convert the drug into its active metabolite (829). Patients with decreased *CYP2C19* function because of genetic polymorphisms metabolize clopidogrel poorly and have higher rates of cardiovascular events after ACS and PCI than patients with normal *CYP2C19* function. The warning also notes that tests are available to identify patients with genetic polymorphisms and that alternative treatment strategies should be considered for patients who are poor metabolizers. The clopidogrel boxed warning leaves the issue of whether to perform *CYP2C19* testing up to the individual physician. It does not specifically require genetic testing or other changes in evaluation or treatment and does not imply that there are solid evidence-based reasons for such actions. Rather, it serves to inform clinicians of genetic variations in response to clopidogrel and to emphasize that clinicians should use this knowledge to make decisions about how to treat individual patients. At the present time, the evidence base is insufficient to recommend routine genetic testing in patients undergoing PCI. There may be a potential role for genetic testing for patients undergoing elective high-risk PCI procedures (e.g., unprotected left main, bifurcating left main, or last patent coronary artery).

6.1.3. Platelet Function Testing: Recommendations

CLASS IIb

1. Platelet function testing may be considered in patients at high risk for poor clinical outcomes (829). *(Level of Evidence: C)*

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

2. In patients treated with clopidogrel with high platelet reactivity, alternative agents, such as prasugrel or ticagrelor, might be considered (829). *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. The routine clinical use of platelet function testing to screen patients treated with clopidogrel who are undergoing PCI is not recommended (829). *(Level of Evidence: C)*

Platelet function testing to tailor antiplatelet therapy has received considerable interest. The GRAVITAS (Gauging Responsiveness With A VerifyNow Assay-Impact On Thrombosis And Safety) trial and several other ongoing trials test the concept that tailoring antiplatelet therapy based on platelet responsiveness assessed in an ex vivo $P2Y_{12}$ assay will improve cardiovascular outcomes (830). In GRAVITAS, treatment with high-dose clopidogrel for 6 months in patients with high platelet reactivity on standard-dose clopidogrel was not beneficial. At the present time, the evidence base is insufficient to recommend routine platelet function testing. The results of 2 ongoing trials (DANTE [Dual Antiplatelet Therapy Tailored on the Extent of Platelet Inhibition] and ARCTIC [Double Randomization of a Monitoring Adjusted Antiplatelet Treatment Versus a Common Antiplatelet Treatment for DES Implantation, and Interruption Versus Continuation of Double Antiplatelet Therapy, One Year After Stenting]) will provide further information on the issue (www.clinicaltrials.gov).

6.2. Stent Thrombosis

The majority of stent thrombosis occurs early (0 to 30 days after PCI). In broad clinical practice, the expected rate of early stent thrombosis is <1%, and beyond 30 days it is 0.2% to 0.6% per year (210,831). Acute stent thrombosis often presents as STEMI, and emergency revascularization is indicated. Acute stent thrombosis is associated with mortality rates of 20% to 45% (832). Survivors are also at risk of recurrent stent thrombosis (833).

Mechanical and pharmacological factors are the most frequent cause of acute stent thrombosis. After the usual measures to restore flow in the infarct-related artery, it is important to consider the etiology of stent thrombosis as it pertains to further therapy and avoidance of recurrence. IVUS may identify factors such as an undersized stent, incomplete stent apposition, residual stenosis, or dissection and can guide subsequent treatment. The most common cause of acute stent thrombosis is nonadherence to DAPT; however, resistance to aspirin or thienopyridines and prothrombotic states such as congenital or acquired thrombophilic states (malignancy) are additional risk factors (834,835).

Given the poor prognosis of stent thrombosis and the uncertainties surrounding treatment, the importance of prevention must be emphasized. This includes ensuring compliance with DAPT and adequate stent sizing and expansion (836).

6.3. Restenosis: Recommendations

CLASS I

1. Patients who develop clinical restenosis after balloon angioplasty should be treated with BMS or DES if anatomic factors are appropriate and if the patient is able to comply with and tolerate DAPT (837). *(Level of Evidence: B)*
2. Patients who develop clinical restenosis after BMS should be treated with DES if anatomic factors are appropriate and the patient is able to comply with and tolerate DAPT (838–840). *(Level of Evidence: A)*

CLASS IIa

1. IVUS is reasonable to determine the mechanism of stent restenosis (495). *(Level of Evidence: C)*

CLASS IIb

1. Patients who develop clinical restenosis after DES may be considered for repeat PCI with balloon angioplasty, BMS, or DES containing the same drug or an alternative antiproliferative drug if anatomic factors are appropriate and the patient is able to comply with and tolerate DAPT (495). *(Level of Evidence: C)*

6.3.1. Background and Incidence

After balloon angioplasty, mechanisms contributing to restenosis include smooth muscle cell migration and proliferation, platelet deposition, thrombus formation, elastic recoil, and negative arterial remodeling. Stents block elastic recoil and negative remodeling, and the predominant mechanism for restenosis after stent implantation is neointimal hyperplasia. Restenosis rates vary, depending on whether angiographic restenosis (defined as >50% diameter stenosis at follow-up angiography) or clinical restenosis (symptomatic and requiring target-lesion revascularization or target-vessel revascularization) is measured, as well as on patient characteristics, coronary anatomy considerations, and device type (balloon angioplasty, BMS, or DES). The incidence of angiographic restenosis rates for uncomplicated lesions treated in RCTs ranges from 32% to 42% after balloon angioplasty (463,464) and from 16% to 32% after BMS (463,464), and is generally <10% after DES (454,841). Less than half of patients with angiographic restenosis present with symptomatic, clinically relevant restenosis at 1-year follow-up, and a pooled analysis of 6,186 patients from 6 trials of BMS showed target-lesion revascularization was performed in 12% and target-vessel revascularization in 14% at 1 year (842,843). Patients with clinical restenosis typically present with recurrent exertional angina, but 5% to 10% of patients present with acute MI and 25% with UA (844,845).

Factors associated with an increased risk of restenosis in various models include clinical setting (STEMI, ACS, daily angina), patient characteristics (diabetes, age <55 to 60 years, prior PCI, male sex, multivessel CAD), lesion location (unprotected left main, SVG), and procedural characteristics (minimum stent diameter ≤2.5 mm, total stent length ≥40 mm) (778,846).

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

PCI strategies for treating restenosis after balloon angioplasty, BMS, and DES are reviewed in the following sections. In addition to repeat PCI, intensified medical therapy or CABG are often also reasonable strategies, dependent on initial treatment (e.g., balloon angioplasty, BMS), pattern of restenosis, likelihood of recurrent restenosis, ability to intensify medical therapy, suitability for CABG, and patient preference. Repeat PCI with BMS or DES is not appropriate if the patient is not able to comply with and tolerate DAPT.

6.3.2. Restenosis After Balloon Angioplasty

For clinical restenosis after balloon angioplasty, stent implantation is superior to repeat balloon angioplasty or atheroablation devices. The REST (REstenosis STent) study showed that target-lesion revascularization rates were 10% for stent-treated patients and 27% for balloon-treated patients ($p=0.001$) (837).

6.3.3. Restenosis After BMS

In-stent restenosis is classified according to these angiographic characteristics: Pattern I includes focal lesions ≤10 mm in length; Pattern II is in-stent restenosis >10 mm within the stent; Pattern III includes in-stent restenosis >10 mm extending outside the stent; and Pattern IV is totally occluded in-stent restenosis (847). Treatment of in-stent restenosis with balloon angioplasty, repeat BMS, or atheroablation devices for Patterns I to IV resulted in 1-year target-lesion revascularization rates of 19%, 35%, 50%, and 83%, respectively. For clinical restenosis after BMS, repeat stenting with DES is preferred. Studies have demonstrated lower recurrent restenosis rates with DES compared with BMS or vascular brachytherapy (495,838–840).

6.3.4. Restenosis After DES

Clinical restenosis after placement of DES is becoming increasingly common due to the large numbers of patients who have been treated with DES. The predominant angiographic pattern for DES in-stent restenosis is focal (≤10 mm in length). Several biologic, mechanical, and technical factors may contribute to DES in-stent restenosis, including drug resistance, hypersensitivity, stent underexpansion, stent strut fracture, nonuniform stent strut coverage, gap in stent coverage, and residual uncovered atherosclerotic lesion. IVUS might be considered to determine the cause for in-stent restenosis and help guide treatment strategy. Interventionists may treat focal DES restenosis with balloon angioplasty and treat nonfocal DES restenosis with BMS, CABG, or repeat DES with the same or an alternative antiproliferative drug (848,849). Small, observational cohort studies have demonstrated angiographic restenosis rates of 25% to 30% with repeat DES either with the same or an alternative drug (495,849,850). There are no RCTs, and the most appropriate treatment of restenosis of DES remains unknown.

6.4. Clinical Follow-Up

At the time of discharge, patients are instructed to contact their physician or seek immediate medical attention if symptoms recur. Most physicians will give the patient instructions on return to work and timing of return to full activities. The importance of strict compliance with aspirin and $P2Y_{12}$ inhibitor therapy is ideally emphasized to the patient at the time of discharge and during follow-up visits.

Secondary prevention measures after PCI are an essential part of long-term therapy, reducing both future morbidity and mortality associated with CAD, and are discussed in Section 6.5. A follow-up visit after PCI is usually scheduled to assess the patient's clinical status, the patient's compliance with secondary prevention therapies, and the success of secondary prevention measures (e.g., blood pressure control, low-density lipoprotein levels, smoking cessation). Routine, periodic stress testing of asymptomatic patients is not considered part of standard patient follow-up.

6.4.1. Exercise Testing: Recommendations

CLASS IIa

1. In patients entering a formal cardiac rehabilitation program after PCI, treadmill exercise testing is reasonable. *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. Routine periodic stress testing of asymptomatic patients after PCI without specific clinical indications should not be performed (795). *(Level of Evidence: C)*

Treadmill exercise testing before cardiac rehabilitation provides information about peak exercise capacity and heart rate, helping to stratify patients for the level of supervision during training, and seems reasonable for this purpose (851); nuclear imaging to assess ischemia in this context usually adds little.

The role of exercise testing to evaluate restenosis is much less certain. Although the presence of symptoms may not be a reliable means of detecting restenosis, there is no evidence that the detection of silent restenosis leads to improved outcome (852,853). Routine testing of all patients after PCI will also lead to many false-positive tests, particularly in the era of DES. As restenosis rates decline from 30% to 10%, the false-positive rate of stress imaging increases from 37% to 77% (854). A recent analysis of a national health insurance claims database and accompanying editorial find that stress testing after PCI is likely overused and rarely leads to repeat revascularization (855,856). In summary, there is no proven benefit or indication for routine periodic stress testing in patients after PCI, and, thus, it is not indicated (8,851). In cases in which there is a clear clinical indication for stress testing in a patient after PCI, exercise ECG alone is an insensitive predictor of restenosis (857,858); therefore, stress imaging is the preferred stress test (8). In cases of recurrent angina after PCI in which the pretest likelihood of restenosis is high and repeat revascularization based on symptoms is likely indicated, most

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

practitioners will proceed directly to cardiac catheterization rather than first obtain stress imaging.

6.4.2. Activity and Return to Work

The timing of return to physical activity depends on the presenting condition as well as previous functional status. For STEMI, for example, daily walking is encouraged immediately, and driving can begin within 1 week after uncomplicated MI if allowed by local motor vehicle laws (859). Sexual activity usually can be resumed within days, provided exercise tolerance is adequate, normally assessed by the ability to climb a flight of stairs (859). Similar recommendations have been issued for UA/NSTEMI (860). Patients with UA who have undergone successful revascularization and are otherwise doing well may return to physical activity on an accelerated schedule, usually within a few days (860).

Return to work is more complex. Return to work rates after MI range from 63% to 94% and are confounded by factors such as job satisfaction, financial stability, and company policies (861). The physical demands and degree of stress of a particular job require that recommendations be individualized. In the PAMI-2 (Primary Angioplasty in Myocardial Infarction) trial, patients were encouraged to return to work 2 weeks after primary PCI for STEMI, and no adverse events were reported (862). In the RITA (Randomized Intervention Treatment of Angina) trial, revascularization with PCI led to earlier return to work compared with CABG, and subsequent employment rates were associated with relief of angina (105). Many practitioners use graded exercise treadmill testing to determine the safety of activity and return to work by measuring the metabolic equivalent of task (MET) level achieved and comparing that level to energy levels required to perform different activities (863).

6.4.3. Cardiac Rehabilitation: Recommendation

CLASS I

1. **Medically supervised exercise programs (cardiac rehabilitation) should be recommended to patients after PCI, particularly for moderate- to high-risk patients for whom supervised exercise training is warranted (796–804). *(Level of Evidence: A)***

Participation in cardiac rehabilitation is associated with significant reductions in all-cause mortality (OR: 0.80, 95% CI: 0.68 to 0.93) and cardiac mortality (796,797). Reports from community-based surveys, which in general enroll older and higher-risk patients than clinical trials, have confirmed that participation in comprehensive rehabilitation is independently associated with a reduction in recurrent MI and reduced mortality (799). Cardiac rehabilitation is also associated with improvements in exercise tolerance, cardiac symptoms, lipid levels, cigarette smoking cessation rates (in conjunction with a smoking cessation program), stress levels, improved medical regimen compliance, and improved psychosocial well-being (800). Cardiac rehabilitation is cost-effective as well (864). Physician referral may be the most powerful predictor of patient participation in a cardiac rehabilitation program (865).

6.5. Secondary Prevention

The treatment of the patient does not end with PCI; secondary prevention measures are a critical component of patient management. Important secondary prevention measures were presented in detail in the "2006 AHA/ACC Guidelines for Secondary Prevention for Patients With Coronary and Other Atherosclerotic Vascular Disease" (562) and have recently been updated in the "AHA/ACCF Secondary Prevention and Risk Reduction Therapy for Patients With Coronary and Other Atherosclerotic Vascular Disease: 2011 Update" (805). The reader is referred to this document for detailed discussions of secondary prevention. Among the important recommendations are the following:

- Lipid management with lifestyle modification *(Class I; Level of Evidence: B)* (805–807) and statin therapy are recommended. *(Level of Evidence: A)* (344,806,808–810,810a) An adequate statin dose should be employed which reduces low-density lipoprotein cholesterol to <100 mg/dL AND achieves at least a 30% lowering of low-density lipoprotein cholesterol. *(Class I; Level of Evidence: C)* (806–810,810a) It is reasonable to treat patients with statin therapy which lowers low-density lipoprotein cholesterol to <70 mg/dL in very high-risk* patients. *(Class IIa; Level of Evidence: C)* (345,808–810,810a,811,812) Patients who have triglycerides ≥200 mg/dL should be treated with statins to lower non–high-density lipoprotein cholesterol to <130 mg/dL. *(Class I; Level of Evidence: B)* (344,809,810,866) In patients who are very high risk* and have triglycerides ≥200 mg/dL, a non–high-density lipoprotein cholesterol goal of <100 mg/dL is reasonable. *(Class IIa; Level of Evidence: C)* (344,809,810,866)
- Blood pressure control with lifestyle modification (*Class I; Level of Evidence: B)* (813–817) and pharmacotherapy (*Class I; Level of Evidence: A)* (805,813,818,819), with the goal of blood pressure <140/90 mm Hg.
- Diabetes management (e.g., lifestyle modification and pharmacotherapy), coordinated with the patient's primary care physician and/or endocrinologist. (*Class I; Level of Evidence: C)* (805)
- Advising patients on the need for complete smoking cessation. *(Class I; Level of Evidence: A)* (805,820–823)

*Presence of established cardiovascular disease plus 1) multiple major risk factors (especially diabetes), 2) severe and poorly controlled risk factors (especially continued cigarette smoking), 3) multiple risk factors of the metabolic syndrome (especially high triglycerides ≥200 mg/dL plus non–high-density lipoprotein cholesterol ≥130 mg/dL with low high-density lipoprotein cholesterol [<40 mg/dL]), and 4) acute coronary syndromes.

7. Quality and Performance Considerations

7.1. Quality and Performance: Recommendations

CLASS I

1. Every PCI program should operate a quality-improvement program that routinely 1) reviews quality and outcomes of the entire program; 2) reviews results of individual operators; 3) includes risk adjustment; 4) provides peer review of difficult or complicated cases; and 5) performs random case reviews. *(Level of Evidence: C)*
2. Every PCI program should participate in a regional or national PCI registry for the purpose of benchmarking its outcomes against current national norms. *(Level of Evidence: C)*

PCI quality and performance considerations are defined by attributes related to structure, processes, and risk-adjusted outcomes. Structural attributes include elements such as equipment, supplies, staffing, institutional and operator-level volumes, and the availability of electronic medical records. Processes include strategies for the appropriate patient, protocols for pre- and postprocedural care, appropriate procedural execution and management of complications, and participation in databases and registries for benchmarking performance of the program and individual operator. Risk-adjusted outcomes are the end result of these structures and processes of care, and when available are more reliable measures of quality than the institutional and individual operator volumes discussed in Section 7.4.

PCI process and outcomes assessments can be used for internal quality-improvement efforts and public reporting. Public reporting of institutional risk-adjusted outcomes is becoming more common. Although operator-level outcomes can be assessed and risk adjusted, the results are much less reliable due to lack of statistical power resulting from lower volumes. Any public reporting must use statistical methods that meet the high criteria established by the AHA Work Group (867).

7.2. Training

The cognitive knowledge and technical skill required to perform PCI continue to grow. Details on the training required for interventional cardiology are found in the most recent ACCF Core Cardiology Training Statement (868).

7.3. Certification and Maintenance of Certification: Recommendation

CLASS IIa

1. It is reasonable for all physicians who perform PCI to participate in the American Board of Internal Medicine interventional cardiology board certification and maintenance of certification program. *(Level of Evidence: C)*

The American Board of Internal Medicine established interventional cardiology board certification in 1999 as an "added qualification" to the cardiovascular disease board certification. Since 1990 all certificates from the American Board of Internal Medicine are time limited for a 10-year period and require all diplomats to participate in maintenance of certification to maintain their board-certified status. Maintenance of certification in interventional cardiology requires physicians to document a minimum of 150 interventional cases over the 2 years before expiration of the current certification, complete self-assessment modules of their medical knowledge, participate in practice-based quality-improvement activities, and pass a secure, knowledge-based examination (869–871). For those who cannot meet the case volume requirement, an alternative option is to submit a log of 25 consecutive cases including patient characteristics and procedural outcomes. The maintenance of certification process is likely to change, as the American Board of Internal Medicine intends to evolve maintenance of certification from an episodic event that occurs once every 10 years to a more continuous process of continuous professional development.

7.4. Operator and Institutional Competency and Volume: Recommendations

CLASS I

1. Elective/urgent PCI should be performed by operators with an acceptable annual volume (≥75 procedures) at high-volume centers (>400 procedures) with on-site cardiac surgery (872,873). *(Level of Evidence: C)*
2. Elective/urgent PCI should be performed by operators and institutions whose current risk-adjusted outcomes statistics are comparable to those reported in contemporary national data registries. *(Level of Evidence: C)*
3. Primary PCI for STEMI should be performed by experienced operators who perform more than 75 elective PCI procedures per year and, ideally, at least 11 PCI procedures for STEMI per year. Ideally, these procedures should be performed in institutions that perform more than 400 elective PCIs per year and more than 36 primary PCI procedures for STEMI per year (872,874–877). *(Level of Evidence: C)*

CLASS IIa

1. It is reasonable that operators with acceptable volume (≥75 PCI procedures per year) perform elective/urgent PCI at low-volume centers (200 to 400 PCI procedures per year) with on-site cardiac surgery (872). *(Level of Evidence: C)*
2. It is reasonable that low-volume operators (<75 PCI procedures per year) perform elective/urgent PCI at high-volume centers (>400 PCI procedures per year) with on-site cardiac surgery. Ideally, operators with an annual procedure volume of fewer than 75 procedures per year should only work at institutions with an activity level of more than 600 procedures per year. Operators who perform fewer than 75 procedures per year should develop a defined mentoring relationship with a highly experienced operator who has an annual procedural volume of at least 150 procedures per year. *(Level of Evidence: C)*

CLASS IIb

1. The benefit of primary PCI for STEMI patients eligible for fibrinolysis when performed by an operator who performs fewer than 75 procedures per year (<11 PCIs for STEMI per year) is not well established. *(Level of Evidence: C)*

CLASS III: NO BENEFIT

1. It is not recommended that elective/urgent PCI be performed by low-volume operators (<75 procedures per year) at low-volume

Downloaded from content.onlinejacc.org by Peter Smith on November 7, 2011

ARTICLE IN PRESS

centers (200 to 400 procedures per year) with or without on-site cardiac surgery. An institution with a volume of fewer than 200 procedures per year, unless in a region that is underserved because of geography, should carefully consider whether it should continue to offer this service (872). *(Level of Evidence: C)*

Older observational evidence supported a volume-outcome relationship in PCI at both the institutional and operator level (873). However, this relationship is complicated and may be inconsistent across low-volume institutions or operators. More recent data on primary PCI suggest that operator experience may modify the volume-outcome relationship at the institutional level (876,878). Risk-adjusted outcomes remain preferable to institutional and individual operator volumes as quality measures.

Operator and hospital volume recommendations have been carried over from the 2005 PCI guideline. However, the writing committee recognizes that these volume recommendations are controversial. In addition, after extensive review of all relevant data, the writing committee believes that the LOE in support of all the above recommendations is best categorized as LOE C rather than LOE B as it has been in prior guidelines for some recommendations. We encourage the ACCF/AHA/ACP Clinical Competence and Training writing group for PCI and other expert writing groups to review this issue so that new recommendations can be considered by the next PCI guideline writing committee.

7.5. Participation in ACC NCDR or National Quality Database

Assessment of PCI quality and outcomes is important both at the level of the entire program and at the level of the individual physician. This requires collection of clinical and procedural data for PCI that allows regular comparison of risk-adjusted outcomes and complications with national benchmarks. The ACC NCDR CathPCI Registry is an example of a national registry to fulfill the goals of assessing and benchmarking quality and outcomes.

8. Future Challenges

Although this latest guideline reflects significant advancements in the field of PCI, there remain future challenges to the formulation and updating of guidelines for PCI. The proliferation of studies comparing the many newer drugs and devices with older therapies (or other newer therapies), often using different or novel study endpoints, endpoint definitions, and noninferiority designs, pose increasing challenges to objectively evaluating newer therapies and generating recommendations for their use. Numerous potential advances in the field of PCI, including intracoronary stem cell infusions for chronic and acute ischemic heart disease, designer drugs, novel intracoronary imaging technologies such as optical coherence tomography and virtual histology, new stent composition and designs (e.g., drug-eluting, biodegradable, bifurcation), and drug-eluting balloons were considered for formal evaluation by the current writing committee, but it was thought that there were insufficient data at present to formulate any formal recommendations on these topics. These and other emerging technologies and treatments will need to be addressed in future PCI guidelines.

Finally, with this proliferation of new technology, the amount of data generated in the evaluation of these potential therapeutic advances will grow dramatically, adding significant challenges to future guideline generations. Of note, the Web site www.clinicaltrials.gov currently lists several hundred PCI-related clinical trials.

This table represents the relationships of committee members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing committee during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$10,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACCF/AHA, a person has a *relevant* relationship IF: a) The *relationship or interest* relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the *document*; or b) The *company/entity* (with whom the relationship exists) makes a drug, drug class, or device addressed in the *document*, or makes a competing drug or device addressed in the *document*; or c) The *person or a member of the person's household* has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the *document*.

*Writing committee members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply. †Significant relationship.

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review and determined to be relevant. It does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$10,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review.

According to the ACCF/AHA, a person has a *relevant* relationship IF: a) The *relationship or interest* relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the *document*; or b) The *company/entity* (with whom the relationship exists) makes a drug, drug class, or device addressed in the *document*, or makes a competing drug or device addressed in the *document*; or c) The *person or a member of the person's household* has a reasonable potential for financial, professional, or other personal gain or loss as a result of the issues/content addressed in the *document*.

*Significant relationship. †No financial benefit.

ACCF indicates American College of Cardiology Foundation; AHA, American Heart Association; DSMB, data safety and monitoring board; NHLBI, National Heart, Lung, and Blood Institute; NIH, National Institutes of Health; SCAI, Society for Cardiovascular Angiography and Interventions; and TIMI, Thrombolysis In Myocardial Infarction.

APPENDIX 3. ABBREVIATION LIST

ACS = acute coronary syndromes
AKI = acute kidney injury
BMS = bare-metal stent(s)
CABG = coronary artery bypass graft surgery
CAD = coronary artery disease
CKD = chronic kidney disease
CTO = chronic total occlusion
DAPT = dual antiplatelet therapy
DES = drug-eluting stent(s)
ECG = electrocardiogram
EF = ejection fraction
EPD = embolic protection device
FDA = U.S. Food and Drug Administration
FFR = fractional flow reserve
GDMT = guideline-directed medical therapy
GI = gastrointestinal
GP = glycoprotein
IABP = intra-aortic balloon pump
IV = intravenous
IVUS = intravascular ultrasound
LAD = left anterior descending
LIMA = left internal mammary artery
LV = left ventricular
LVEF = left ventricular ejection fraction
MACE = major adverse cardiac event
MI = myocardial infarction
MRI = magnetic resonance imaging
NCDR = National Cardiovascular Data Registry
PCI = percutaneous coronary intervention
PPI = proton pump inhibitor
RCT = randomized controlled trial
SIHD = stable ischemic heart disease
STEMI = ST-elevation myocardial infarction
SVG = saphenous vein graft
TIMI = Thrombolysis In Myocardial Infarction
TMR = transmyocardial laser revascularization
UA/NSTEMI = unstable angina/non–ST-elevation myocardial infarction
UFH = unfractionated heparin

Appendix 4B. The SCAI Lesion Classification System

Type I lesions (highest success expected, lowest risk)

1. Does not meet criteria for C lesion
2. Patent

Type II lesions

1. Meets any of these criteria for ACC/AHA C lesion
   - Diffuse (>2 cm length)
   - Excessive tortuosity of proximal segment
   - Extremely angulated segments, >90°
   - Inability to protect major side branches
   - Degenerated vein grafts with friable lesions
2. Patent

Type III lesions

1. Does not meet criteria for C lesion
2. Occluded

Type IV lesions

1. Meets any of these criteria for ACC/AHA C lesion
   - Diffuse (>2 cm length)
   - Excessive tortuosity of proximal segment
   - Extremely angulated segments, >90°
   - Inability to protect major side branches
   - Degenerated vein grafts with friable lesions
   - Occluded for >3 mo
2. Occluded

ACC indicates American College of Cardiology; AHA, American Heart Association; and SCAI, Society for Cardiovascular Angiography and Interventions. Reprinted with permission from Krone et al. (879).

Appendix 4C. Strategies to Reduce Radiation Exposure to Patient and Operator

Precautions to minimize exposure to patient and operator

- Use radiation only when imaging is necessary to support clinical care
- Minimize use of cine
- Minimize use of steep angles of x-ray beam
- Minimize use of magnification modes
- Minimize frame rate of fluoroscopy and cine
- Keep the image receptor close to the patient
- Utilize collimation to the fullest extent possible
- Monitor radiation dose in real time to assess patient risk-benefit during procedure

Precautions to specifically minimize exposure to operator

- Use and maintain appropriate protective garments
- Maximize distance of operator from x-ray source and patient
- Keep above-table and below-table shields in optimal position at all times
- Keep all body parts out of field of view at all times

Precautions to specifically minimize exposure to patient

- Keep table height as high as comfortably possible for operator
- Vary imaging beam angle to minimize exposure to any single skin area
- Keep patient's extremities out of beam

Appendix 4D. Patient Care Consideration Based on Procedural Radiation Dose

$K_{a,r}$*	P_{KA}†	FT‡	Action
>5 Gray	>500 Gray cm^2	>60 min	Physician charts documentation about why exposure at this level occurred, documents whether multiple skin entry angles were used, assesses risk, educates patient about potential for skin injury, and arranges for appropriate follow-up within 30 d. Phone calls may be sufficient with an office visit arranged if issues/questions arise or a potential tissue injury is suspected.
≥10 Gray			Physician contacts radiation safety officer/medical physicist. The radiation safety officer/medical physicist should perform a detailed analysis of PSD. Document a) FOV, b) skin entrance port number, c) known geometry, with a "rough" geometric setup required. Educate patient about the potential for skin injury and document this in chart. Schedule an office visit in 2 to 4 wk.
PSD§ >15 Gray			If calculated PSD is indeed >15 Gray, the physician and/or radiation safety officer/medical physicist should contact hospital risk management within 24 h. Report the event to the Joint Commission and as needed to the appropriate State Department of Health.

*$K_{a,r}$ is total air kerma at reference point; †P_{KA} is air kerma-area product; ‡FT is total fluoroscopy time, does not include cine; §PSD is peak skin dose, which requires calculations made by a qualified physicist.

FOV indicates field of view; and FT, fluoroscopy time.

Appendix 4E. General Considerations in Deciding Between Early Invasive Strategy and Initial Conservative Strategy

Early Invasive Strategy Generally Preferred	Initial Conservative Strategy Generally Preferred or Reasonable
• Recurrent angina or ischemia at rest or with low-level activities despite intensive medical therapy • Elevated cardiac biomarkers (TnT or TnI) • New or presumably new ST-segment depression • Signs or symptoms of heart failure • Hemodynamic instability • High-risk score (e.g., GRACE, TIMI) • Sustained ventricular tachycardia • PCI within 6 mo • Prior CABG • Diabetes mellitus • Mild to moderate renal dysfunction • Reduced LV function (LVEF <40%)	• Low-risk score (e.g., GRACE, TIMI) • Absence of high-risk features • High risk for catheterization-related complications • Patient not a candidate for revascularization (with either PCI or CABG) • Patient prefers conservative therapy

CABG indicates coronary artery bypass graft surgery; GRACE, Global Registry of Acute Coronary Events; LV, left ventricular; LVEF, left ventricular ejection fraction; PCI, percutaneous coronary intervention; TIMI, Thrombolysis In Myocardial Infarction; TnI, troponin I; and TnT, troponin T.

Appendix 4F. Agents for Procedural Sedation and Analgesia

Drug	Clinical Effects	Dose	Onset	Duration	Comments
Midazolam	Sedation, anxiolysis. No analgesia.	Initial 0.5 to 1 mg IV, then titrated.	2 to 3 min	45 to 60 min	Reduce dose when used in combination with opioids. May produce paradoxical excitement. Reversible with flumazenil.
Fentanyl	Analgesia	50 mcg IV. May repeat every 3 min, titrate to effect.	3 to 5 min	30 to 60 min	Reduce dosing when combined with benzodiazepines. Reversible with naloxone.
Etomidate	Sedation, anxiolysis. No analgesia.	Sedation: 0.1 mg/kg IV; repeat if inadequate response.	<1 min	5 to 15 min	Respiratory depression may occur; institutional guidelines vary about administration to nonintubated patients by nonanesthesiologists. May cause myoclonus, nausea, and vomiting. Adrenocortical suppression occurs but is rarely of clinical significance. Not reversible.
Propofol	Sedation, anxiolysis. No analgesia.	Load 1 mg/kg IV; may administer additional 0.5 mg/kg doses as needed to enhance or prolong sedation.	<1 min	5 to 15 min	Frequent hypotension and respiratory depression; institutional guidelines vary concerning administration to nonintubated patients by nonanesthesiologists. Avoid with egg or soy allergies. Not reversible.
Reversal Agents					
Naloxone	Opioid reversal	0.4 to 2 mg IV	2 min	20 to 40 min	If shorter acting than reversed drug, serial doses may be required.
Flumazenil	Benzodiazepine reversal	0.2 mg IV. May repeat every 1 min up to 1 mg.	1 to 2 min	30 to 60 min	If shorter acting than reversed drug, serial doses may be required. Do not use in patients receiving long-term benzodiazepines, cyclosporine, isoniazid, lithium, propoxyphene, theophylline, or tricyclic antidepressants.

IV indicates intravenous.

Introduction

Optimal revascularization strategy in patients with coronary artery disease remains a subject of debate between interventional cardiologists and surgeons. Numerous large scale randomized trials addressed this issue comparing coronary artery bypass grafting (CABG) with percutaneous coronary intervention (PCI) in patients with multivessel disease (MVD). Initially these trials compared multivessel balloon angioplasty with CABG[1-6] and in a later period multivessel stenting with CABG[7-11]. These studies clearly demonstrated that there was no difference between the two therapeutic modalities regarding mortality and non fatal myocardial infarction but patients treated with balloon angioplasty or stenting required more often repeat revascularization procedures related to restenosis[12,13].

Clearly stenting reduced the gap in the event free survival rate between the two revascularization strategies from 32% in CABRI trial (91% versus 59% in favour of CABG) to 14% in ARTS I trial (89% versus 75%) but still surgery remained the gold standard for patients with MVD with an event free survival rate around 90%[14].

Recently the drug eluting stents were introduced and proven to be very effective in reducing restenosis and the incidence of repeat revascularisation[15-18]. In the recently conducted ARTS II trial the sirolimus eluting stents were compared with historical CABG data from the ARTS I trial in patients with MVD. The incidence of major adverse cardiac events was comparable in both approaches, even though the number of vessels and lesions treated were higher than in the previous trials[19]. However, it has been argued that despite the fact that patients with two or three vessel disease have been included in the aforementioned trials, in the "real world" both interventional cardiologists and surgeons are often confronted with more complex anatomy. Numerous exclusion criteria and disagreement between the surgeons and the interventional cardiologists allowed only 2%-12% of the patients screened to be randomized[13].

Another characteristic of these trials was the heterogeneity in the complexity of coronary artery disease of the patients enrolled[13]. For example, a patient with distal a left-main stem trifurcation lesion in combination with an occluded right coronary artery is pooled together with a patient with three focal lesions in the mid portions of the three coronary arteries. Both are characterised as routinely named “3-vessel disease”, despite the fact that the first patient represents a greater therapeutic challenge for the interventional cardiologist and has completely different prognosis compared to the second patient regardless of the revascularization strategy; percutaneous or surgical. The absence of grading of the severity of coronary artery disease and the lack of comparison of lesion complexity based on pre-treatment angiographic criteria between various groups severely limits the interpretation of the results of these trials.

Thus, for the selection of the optimal revascularization strategy for patients with three vessel and/or left main stem disease there are three major requirements:

1. The conductance of an "all comer" (no exclusion criteria) study in such patients.
2. Consensus between the interventional cardiologist and the cardiothoracic surgeon for the treatment plan.
3. The quantification of the complexity of coronary artery disease, taking into account not only the number of significant lesions and their location, but also the complexity of each lesion independently.

The SYNTAX (SYNergy between PCI with TAXUS™ and Cardiac Surgery) study was organized as an all comer study for patients with significant lesions in the left main stem and/or the three epicardial coronary arteries. It will be comprised of a randomized arm and two registries for patients that are not suitable for one of the two revascularization strategies. Patients who have a preference for one of the treatment strategies or patients in whom medical treatment is suggested they will be included in the screening log.

The SYNTAX score has been developed for this study to prospectively characterise the coronary vasculature with respect to the number of lesions and their functional impact, location, and complexity. Higher SYNTAX scores, indicative of more complex disease are hypothesized to represent a bigger therapeutic challenge and to have potentially worse prognosis.

Pre-existing classifications

The SYNTAX score has been developed based on the following:

1. The AHA classification of the coronary tree segments modified for the ARTS study
2. The Leaman score
3. The ACC/AHA lesions classification system
4. The total occlusion classification system
5. The Duke and ICPS classification systems for bifurcation lesions
6. Consultation of experts

Each of these classifications has been focusing on specific functional and anatomical parameters of the lesions. Thus, the development of a global classification system that would take into account all the variables was necessary.

Definition of the coronary tree segments

The definition of the coronary tree segments is based on the classification proposed by the AHA[20] and modified for the ARTS I and II trials[21]. By this system the arterial tree is divided in 16 segments (Figure 1) and as such has been adopted in the SYNTAX score.

Leaman score[22]

The 'Leaman score' is based on the severity of luminal diameter narrowing and weighed according to the usual blood flow to the left ventricle in each vessel or vessel segment. In a right dominant system, the right coronary artery (RCA) supplies approximately 16% and the left coronary artery (LCA) 84% of the flow to the left ventricle (LV). This 84% is normally directed for 66% to the left anterior descending artery (LAD), and for 33% into the left circumflex coronary artery (LCX). Thus, the Left Main (LM) supplies approximately 5 times, the LAD approximately 3,5 times (84/16 x 0.66) and the circumflex 1,5 times as much blood as the RCA to the left ventricle. In a left dominant system the RCA does not contribute to the blood supply of the ventricle. Thus the LM supplies 100% of the flow to the LV. The RCA contribution of blood flow to the LV is now supplied by the LCX. Hence the LAD provides 58% (weighing factor 3.5) and the LCX 42% (weighing factor 2.5) of the total flow to the LV. Using the same principle of relative blood supply to the LV all coronary segments has been given a weighing factor factor, Table 1.

The contribution of each coronary segment to the blood flow to the LV is used as a multiplication factor for the calculation of the Leaman score and as such has been transferred to the SYNTAX score.

A lesion is defined as significant when it causes (50% reduction in luminal diameter by visual assessment in vessels (1.5mm. Less severe lesions should not be included in the SYNTAX score. The percent diameter stenosis is not considered in the algorithm. Distinction has been made only between occlusive (100% diameter stenosis) and non occlusive (50-99% diameter stenosis) disease. A multiplication factor of 2 is used for non-occlusive lesions and 5 for occlusive lesions reflecting the difficulty of the percutaneous treatment, Table 1. Importantly, all other adverse lesion characteristics considered in the SYNTAX score have an additive value, Table 2.

Table 1. Segment weighing factors

Segment No		Right dominance	Left dominance
1	RCA proximal	1	0
2	RCA mid	1	0
3	RCA distal	1	0
4	Posterior descending artery	1	n.a.
16	Posterolateral branch from RCA	0.5	n.a.
16a	Posterolateral branch from RCA	0.5	n.a.
16b	Posterolateral branch from RCA	0.5	n.a.
16c	Posterolateral branch from RCA	0.5	n.a.
5	Left Main	5	6
6	LAD proximal	3.5	3.5
7	LAD mid	2.5	2.5
8	LAD apical	1	1
9	First diagonal	1	1
9a	First diagonal[a]	1	1
10	Second diagonal	0.5	0.5
10a	Second diagonal[a]	0.5	0.5
11	Proximal circumflex artery	1.5	2.5
12	Intermediate/ anterolateral artery	1	1
12a	Obtuse marginal[a]	1	1
12b	Obtuse marginal[b]	1	1
13	Distal circumflex artery	0.5	1.5
14	Left posterolateral	0.5	1
14a	Left posterolateral[a]	0.5	1
14b	Left posterolateral[b]	0.5	1
15	Posterior descending	n.a.	1

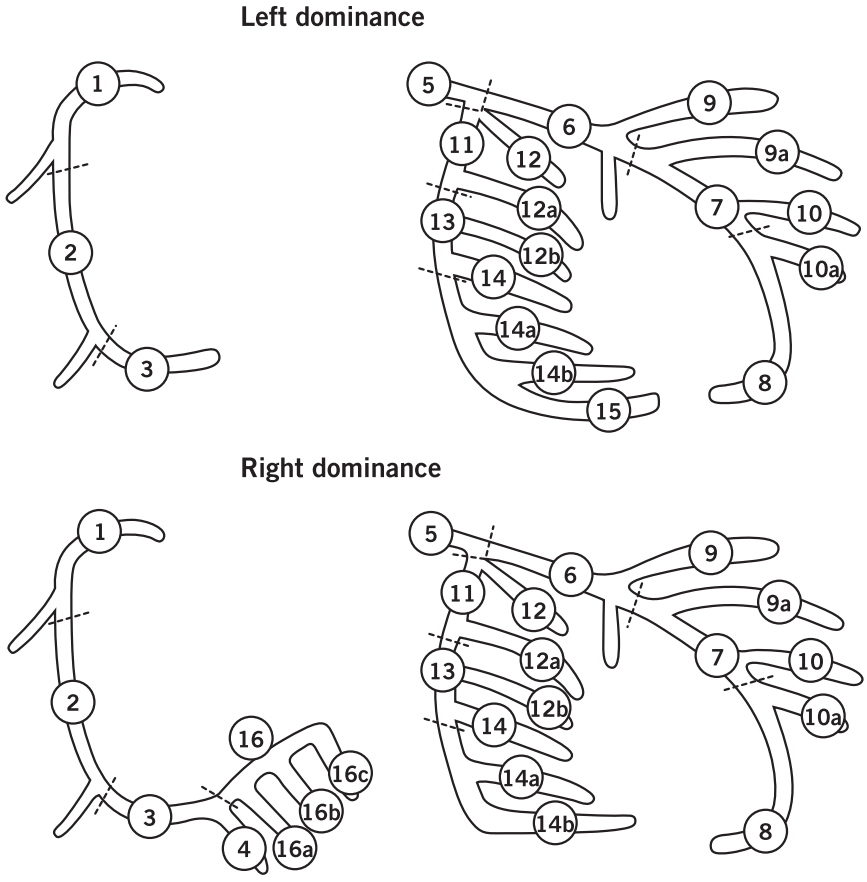

Figure 1. Definition of the coronary tree segments

1. *RCA proximal: From the ostium to one half the distance to the acute margin of the heart.*

2. *RCA mid: From the end of first segment to acute margin of heart.*

3. *RCA distal: From the acute margin of the heart to the origin of the posterior descending artery.*

4. *Posterior descending artery: Running in the posterior interventricular groove.*

16. *Posterolateral branch from RCA: Posterolateral branch originating from the distal coronary artery distal to the crux.*

16a. *Posterolateral branch from RCA: First posterolateral branch from segment 16.*

16b. *Posterolateral branch from RCA: Second posterolateral branch from segment 16.*

16c. *Posterolateral branch from RCA: Third posterolateral branch from segment 16.*

5. *Left main: From the ostium of the LCA through bifurcation into left anterior descending and left circumflex branches.*

6. *LAD proximal: Proximal to and including first major septal branch.*

7. *LAD mid: LAD immediately distal to origin of first septal branch and extending to the point where LAD forms an angle (RAO view). If this angle is not identifiable this segment ends at one half the distance from the first septal to the apex of the heart.*

8. *LAD apical: Terminal portion of LAD, beginning at the end of previous segment and extending to or beyond the apex.*

9. *First diagonal: The first diagonal originating from segment 6 or 7.*

9a. *First diagonal a: Additional first diagonal originating from segment 6 or 7, before segment 8.*

10. *Second diagonal: Originating from segment 8 or the transition between segment 7 and 8.*

10a. *Second diagonal a: Additional second diagonal originating from segment 8.*

11. *Proximal circumflex artery: Main stem of circumflex from its origin of left main and including origin of first obtuse marginal branch.*

12. *Intermediate/anterolateral artery: Branch from trifurcating left main other than proximal LAD or LCX. It belongs to the circumflex territory.*

12a. *Obtuse marginal a: First side branch of circumflex running in general to the area of obtuse margin of the heart.*

12b. *Obtuse marginal b: Second additional branch of circumflex running in the same direction as 12.*

13. *Distal circumflex artery: The stem of the circumflex distal to the origin of the most distal obtuse marginal branch, and running along the posterior left atrioventricular groove. Caliber may be small or artery absent.*

14. *Left posterolateral: Running to the posterolateral surface of the left ventricle. May be absent or a division of obtuse marginal branch.*

14a. *Left posterolateral a: Distal from 14 and running in the same direction.*

14b. *Left posterolateral b: Distal from 14 and 14 a and running in the same direction.*

15. *Posterior descending: Most distal part of dominant left circumflex when present. It gives origin to septal branches. When this artery is present, segment 4 is usually absent.*

Table 2. Lesions adverse characteristic scoring

Diameter reduction*		
- Total occlusion		x5
- Significant lesion (50-99%)		x2
Total occlusion (TO)		
- Age >3months or unknown		+1
- Blunt stump		+1
- Bridging		+1
- First segment visible beyond TO		+1/ per non-visible segment
- Side branch (SB)	- Yes, SB <1.5mm**	+1
	- Yes, both SB < & ≥ 1.5mm	+1
Trifurcations		
- 1 diseased segment		+3
- 2 diseased segments		+4
- 3 diseased segments		+5
- 4 diseased segments		+6
Bifurcations		
- Type A, B, C		+1
- Type D, E, F, G		+2
- Angulation <70°		+1
Aorto ostial stenosis		+1
Severe tortuosity		+2
Length > 20mm		+1
Heavy calcification		+2
Thrombus		+1
"Diffuse disease"/small vessels		+1/ per segment number

x: multiplication
+: addition

* In the SYNTAX algorithm there is no question for % luminal diameter reduction. The lesions are considered as significant (50-99% luminal diameter reduction) or occlusive.

** If all the side branches are 1.5mm in diameter, no points are added since the lesion is considered as a bifurcation and it will be scored as such.

Multiple-tandem lesions

If multiple lesions are less than 3 vessel reference diameters apart (tandem lesion), these lesions are scored as one lesion. However, lesions at a greater distance from each other (more than 3 vessel reference diameters), are considered as separate lesions.

ACC/AHA lesion classification system[23]

This lesion classification system is based on parameters, such as length, eccentricity, angulation, calcification, involvement of side branches, thrombus and severity of stenosis. Lesions are classified as Type A, (high success and low risk), Type B (moderate success and moderate risk) or Type C (low success and high risk).
The majority of these individual parameters have been incorporated in the SYNTAX score (Table 2). Although the ACC/AHA system takes into account the total occlusions and the bifurcation lesions classifying them as a high-risk, it is not considered as detailed enough to adequately quantify their complexity.

Total occlusion classification system[24]

A lesion is characterized as a total occlusion when no antegrade flow is visible distal to the obstruction. Segments distal to the occlusion may be filled by bridging, ipsilateral or contra-lateral collaterals. Parameters suggested in this system such as age of the occlusion more than three months, presence of side-branch at the site of the occlusion and their size, a blunt stump, presence of bridging collaterals and occlusion length have been incorporated into the SYNTAX score, Table 2.
The length of the obstructed segment is calculated by measuring the distance between the stump of the occlusion and the first segment beyond the occlusion, visualized by ante-grade or retrograde collateral flow, Figure 2. The age of the total occlusion is scored based on history of previous infarct, worsening symptoms, previous angiographic or electrocardiographic data. In case that this information is absent the age of total occlusion is scored as unknown.

Duke and ICPS bifurcation lesion classification systems

Bifurcation is defined as a junction of a main vessel and a side branch (with a minimal diameter of 1.5mm). A lesion is scored as a bifurcation, if the main vessel and/or the side branch have a narrowing. Bifurcation lesions *not involving the ostium* of the side branch are classified as type A if the lesion in the main vessel is proximal, type B distal and type C both proximal and distal to the side branch. Bifurcation lesions *involving the ostium* of the side branch are classified as type F if the lesion in the main branch is proximal, type G distal and type D both proximal and distal to the side branch. As plaque shift can occur even when only the ostium of a side branch is narrowed, such a lesion is also considered as a bifurcation (type E) (Figure 3). Bifurcations are only considered for the following segment junctions: 5/6/11, 6/7/9, 7/8/10, 11/13/12a, 13/14/14a and 3/4/16 and 13/14/15 in case of left dominance. The above mentioned classification is a combination of the Duke[25] and the ICPS[26] classification bifurcation systems, each proposing 6 types of bifurcations. Type G was missing from the former while type D from the latter. The combination of both constitutes the SYNTAX classification with 7 types.
One lesion characteristic added to the bifurcation lesion classification is the angulation less than 70 degrees of the side branch with the distal main vessel. Despite the fact that this represents a less technical challenge, it is regarded as an adverse lesion characteristic due to the fact that the smaller this angle is the more difficult it will be to cover the ostium of the side branch when stenting is necessary, Figure 4.

Trifurcation lesions

Trifurcation is a junction of three branches, one main vessel and two side branches (with a minimal diameter of 1.5mm). In a trifurcation, one, two, three or four of the involved segments can be diseased. The most common example of a trifurcation is at the division of LM into the LAD, LCX, and an intermediate branch. Trifurcations are only scored for the following segment junctions: 3/4/16/16a, 5/6/11/12, 11/12a/12b/13, 6/7/9/9a and 7/8/10/10a, Table 2.

EUROPCRONLINE.COM

Aorto-ostial lesions

A lesion is classified as aorto-ostial when it is located immediately at the origin of the coronary arteries from the aorta. It applies only to segments 1 and 5. In case of absence of a LM (double ostium of the Left Coronary Artery), the segments 6 of the LAD and 11 of the LCX originate directly from the aorta and consequently may also involve aorto-ostial lesions. Aorto-ostial location is regarded as an adverse characteristic since the treatment of such lesions is technically more challenging.

Diffuse disease/Small vessels

Present when at least 75% of the length of the segment distal to the lesion has a vessel diameter of <2mm, irrespective of the presence or absence of disease at that distal segment. It is a parameter introduced to reflect the more challenging creation of a surgical anastomosis in small or diseased vessels.

The SYNTAX score algorithm (Table 3)

The SYNTAX score is calculated by a computer program consisting of sequential and interactive self-guided questions. The algorithm consists of twelve main questions. They can be divided in two groups:
The first three determine the dominance, the total number of lesions and the vessel segments involved per lesion and they appear once. The maximum number of lesions allowed is twelve and each lesion is characterized by a number, 1 to 12. The lesions will be scored in the numerical order inserted in question 3. Each lesion can involve one or more segments. In this case each vessel segment involved contributes to the lesion scoring. There is no limit in the number of segments involved per lesion.
The last nine questions refer to adverse lesion characteristics and are repeated for each lesion.
The question referring to a total occlusion is the first one. If a total occlusion is scored, answers must be given to detailed sub-questions. The last of these sub-questions refers to the presence or absence of side branches and their size. If there are no side branches or if their diameter is <1.5 mm then the questions related to the trifurcation and bifurcation lesions will be automatically skipped since vessels <1.5 mm are not considered large enough for treatment either with PCI or CABG. If side branches with diameter 1.5 mm are involved then the lesion is considered as both total occlusion and bifurcation lesion and the algorithm will continue with all the questions. The same is the case for non-occlusive lesions. With the exception of the selection of the type in case of a bifurcation or a trifurcation lesion all the other questions of the algorithm can be answered by selecting “yes” or “no”.

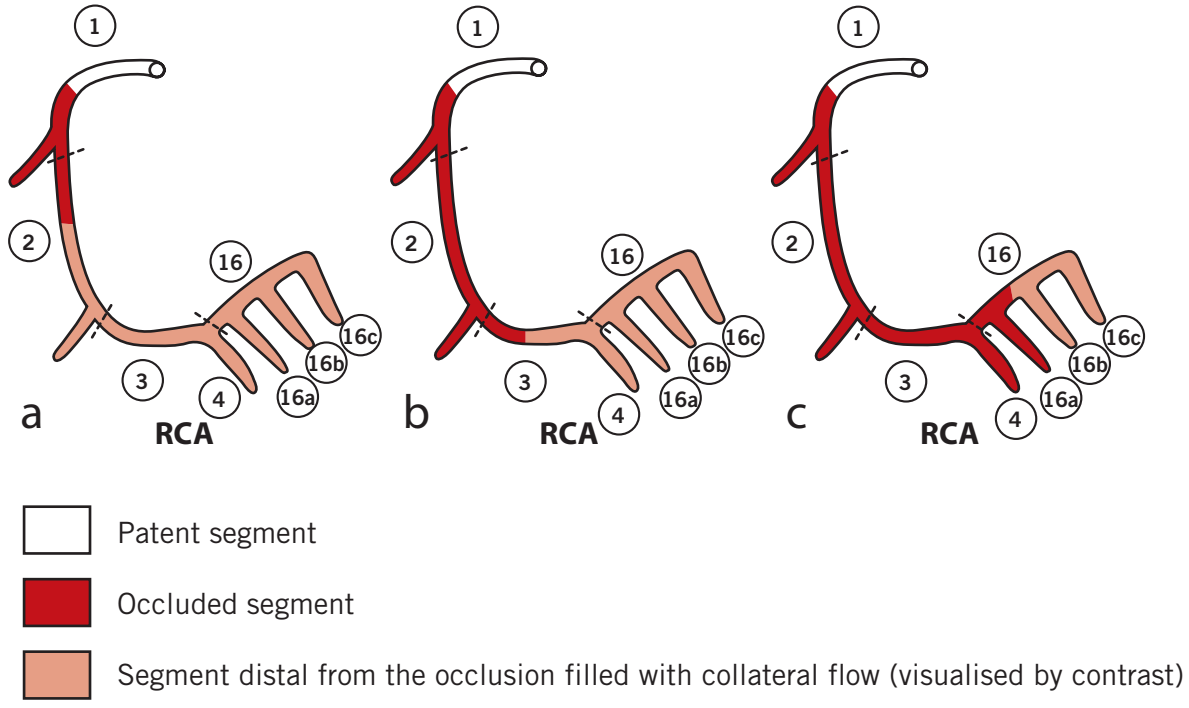

Figure 2. Total occlusion length assessment
a) Total occlusion involving segments 1 and 2. Segments 2,3,4,16,16a,16b,16c are filled by antegrade or retrograde collateral flow (visualised by contrast).
b) Total occlusion involving segments 1, 2 and 3. Segments 3,4,16,16a,16b,16c are filled by antegrade or retrograde collateral flow (visualised by contrast).
c) Total occlusion involving segments 1, 2, 3, 4, 16 and 16a Segments 16,16b,16c are visualized by antegrade or retrograde collateral flow (visualised by contrast).

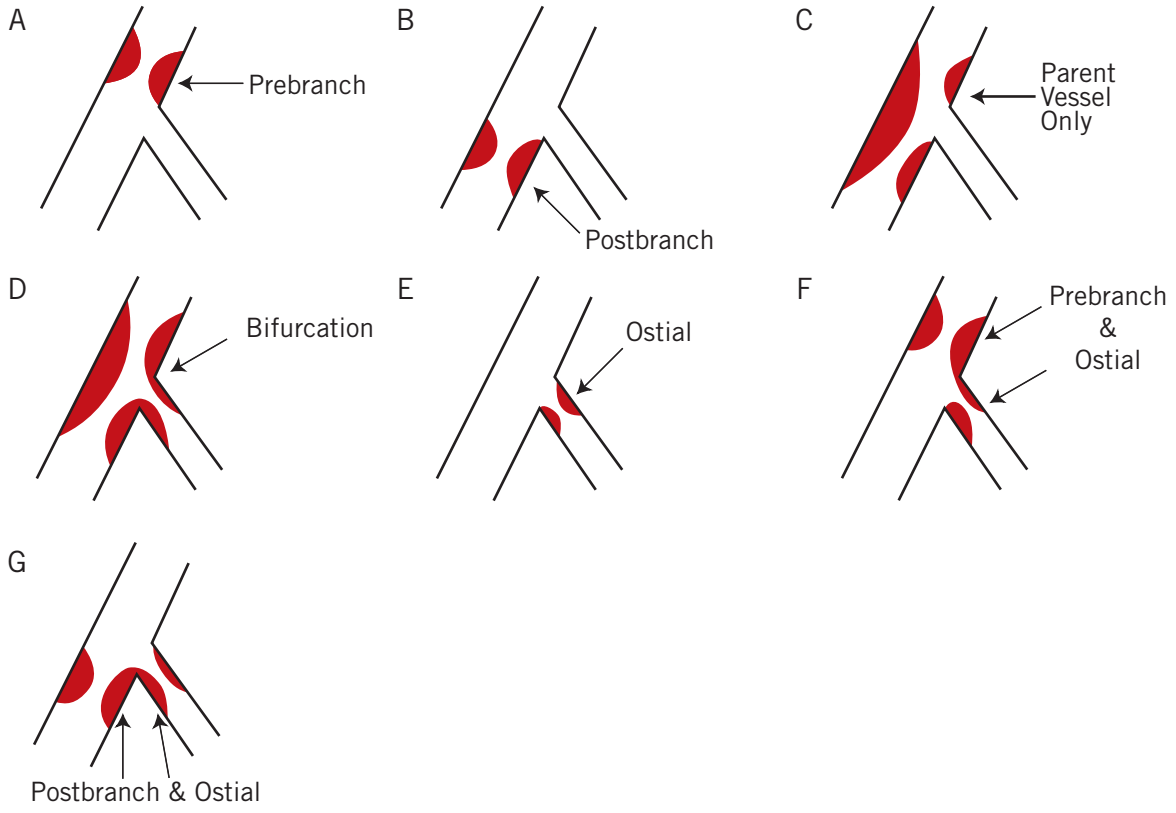

Figure 3. Bifurcation classification (modified from Duke and ICPS classifications systems)
Type A: *Pre-branch stenosis not involving the ostium of the side branch.*
Type B: *Post side branch stenosis of the main vessel not involving the origin of the side branch.*
Type C: *Stenosis encompassing the side branch but not involving its ostium.*
Type D: *Stenosis involving the main vessel and ostium of the side branch.*
Type E: *Stenosis involving only the ostium of the side branch*
Type F: *Stenosis directly involving the main vessel (pre-side branch) and the ostium of the side branch.*
Type G: *Stenosis directly involving the main vessel (post-side branch) and the ostium of the side branch.*

The last question of the algorithm, diffuse disease/small vessels, is the only one non-lesion-specific since it is related to vessel anatomy beyond the stenosis. In case of positive answer all the coronary segments beyond the one under scoring will appear allowing the selection of these fulfilling the criteria for diffuse disease/small vessels. It is quoted once (the first time selected) per coronary territory (RCA, LM, LAD, LCX). If for example this question is answered during a LM lesion scoring it will not reappear for lesions in the LAD or LCX territory. The same is the case for multiple lesions in the same vessel. Since the lesions are scored in the numerical order inserted in question 3, a scoring in "anatomical order" from proximal to distal is advised for each coronary artery. For example a lesion in segment 2 of the RCA should be scored before a lesion located in more distal segments.

An important characteristic of the SYNTAX score is that it is lesion based. For each lesion a separate score is calculated. The total SYNTAX score is derived from the summation of these individual scorings. After the completion of the algorithm a report is automatically generated summarizing all the adverse characteristics, and the individual scoring of each lesion as well as the total SYNTAX score. Two examples of the SYNTAX score calculation are presented in Figures 5, 6. Both patients have significant stenosis in all three

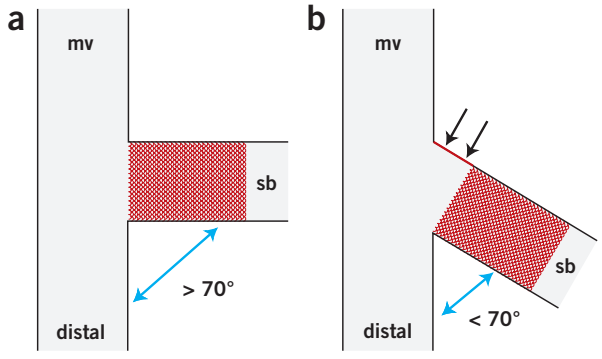

Figure 4.
a) An example of a bifurcation lesion with a wide angle (>70 degrees) between the side branch and the distal main vessel. Although technical challenging sometimes, the stent can fully cover both the proximal and distal rims of the side branch ostium. b) An example of a bifurcation with a steep angle (<70 degrees) between the side branch and the distal main vessel. Side branch stenting might be technically less challenging compared to the previous anatomy but when the stent is placed to cover the distal rim of the ostium the proximal rim will remain uncovered (red line with arrows). If the stent is placed to cover the proximal rim it will protrude into the main vessel distally. mv denotes main vessel, sb denotes side branch.

11. Thrombus

12. Diffuse disease/small vessels

i. Number of segments with diffuse disease/small vessels

The SYNTAX score is calculated by a computer program consisting of sequential and interactive self-guided questions. All the below mentioned definitions are projected in a side window when the signal (i) indicating information, available for each questions, is pointed with the cursor.

Definitions:

Dominance: a) Right dominance: the posterior descending coronary artery is a branch of the right coronary artery (segment 4). b) Left dominance: the posterior descending artery is a branch of the left coronary artery (segment 15). Co-dominance does not exist as an option at the SYNTAX score.

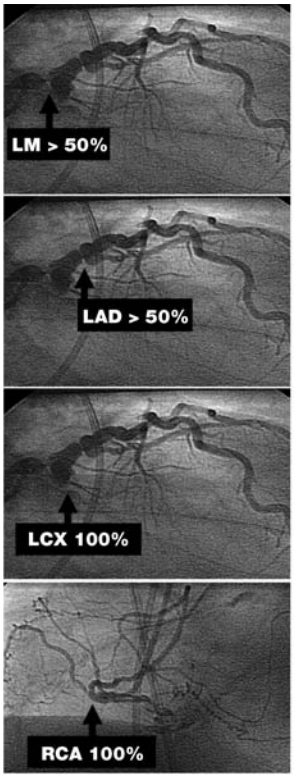
Total occlusion: TIMI 0 flow: no perfusion; no antegrade flow beyond the point of occlusion

Bridging collaterals: Small channels running in parallel to the vessel and connecting proximal vessel to distal and being responsible for the ipsilateral collateralization

Trifurcation: A junction of three branches, one main vessel and two side-branches. Trifurcations are only scored for the following segment junctions: 3/4/16/16a, 5/6/11/12, 11/12a/12b/13, 6/7/9/9a and 7/8/10/10a

Bifurcation: A junction of a main vessel and a side branch of at least 1.5mm in diameter. Bifurcations are only scored for the following segment junctions: 5/6/11, 6/7/9, 7/8/10, 11/13/12a, 13/14/14a, 3/4/16 and 13/14/15. Bifurcation lesions may involve one segment (types A, B and E), two segments (types C, F and G) or three segments (type D).

Aorto ostial: A lesion is classified as aorto-ostial when it is located immediately at the origin of the coronary vessels from the aorta (applies only to segments 1 and 5, or to 6 and 11 in case of double ostium of the LCA).



Severe tortuosity: One or more bends of 90° or more, or three or more bends of 45° to 90° proximal of the diseased segment.

Length >20mm: Estimation of the length of that portion of the stenosis that has ≥ 50% reduction in luminal diameter in the projection where the lesion appears to be the longest. (In case of a bifurcation lesion at least one of the branches has a lesion length of >20mm).

Heavy calcification: Multiple persisting opacifications of the coronary wall visible in more than one projection surrounding the complete lumen of the coronary artery at the site of the lesion.

Thrombus: Spheric, ovoid or irregular intraluminal filling defect or lucency surrounded on three sides by contrast medium seen just distal or within the coronary stenosis in multiple projections or a visible embolization of intraluminal material downstream.

Diffuse disease/small vessels: More than 75% of the length of the segment has a vessel diameter of 2mm, irrespective of the presence or absence of a lesion.

SYNTAX SCORE 17

Figure 6.

coronary arteries with four lesions each but the calculated SYNTAX score differs greatly (54.5 versus 17) reflecting the more complex pattern of coronary artery disease in the patient with the higher score.

Validation

The utility of the SYNTAX score for predicting outcomes will be examined at three junctures in the conduct of the trial:

1. In phase I it will be evaluated based on patient allocation into the 3 study arms (randomized, PCI registry and CABG registry).
2. In phase II its utility at predicting early procedural outcomes (30 days) will be assessed and optimised.
3. In phase III it will be evaluated and the scoring will be optimized for predicting 1, 3 and 5 year outcomes.

Summary

The most important characteristic of the SYNTAX score to be emphasized is that it is focusing on anatomy of coronary vasculature and not on treatment plan.

The ultimate goal is to create an angiographic tool grading the complexity of coronary artery disease and obtain evidence based guidelines for selecting the optimal technique of revascularization (CABG or PCI). In addition it will allow comparison of coronary artery disease complexity in individual patients and entire patient cohorts, as well as assessment of adequacy and completeness of revascularisation.

In summary it's a score under investigation to predict prognosis based on disease complexity in coronary vasculature. It will be retroactively weighted based on clinical outcomes and potentially revised to optimize its prognostic value. Once validated and standardised the SYNTAX score will become available on-line.

ABSTRACT

BACKGROUND

Percutaneous coronary intervention (PCI) involving drug-eluting stents is increasingly used to treat complex coronary artery disease, although coronary-artery bypass grafting (CABG) has been the treatment of choice historically. Our trial compared PCI and CABG for treating patients with previously untreated three-vessel or left main coronary artery disease (or both).

METHODS
